Criteria for inclusion in the Public Health Research journal

Reports are published in *Public Health Research* (PHR) if (1) they have resulted from work for the PHR programme, and (2) they are of a sufficiently high scientific quality as assessed by the reviewers and editors.

Reviews in *Public Health Research* are termed 'systematic' when the account of the search, appraisal and synthesis methods (to minimise biases and random errors) would, in theory, permit the replication of the review by others.

PHR programme

The Public Health Research (PHR) programme, part of the National Institute for Health Research (NIHR), evaluates public health interventions, providing new knowledge on the benefits, costs, acceptability and wider impacts of non-NHS interventions intended to improve the health of the public and reduce inequalities in health. The scope of the programme is multi-disciplinary and broad, covering a range of interventions that improve public health. The Public Health Research programme also complements the NIHR Health Technology Assessment programme which has a growing portfolio evaluating NHS public health interventions.

For more information about the PHR programme please visit the website: http://www.nets.nihr.ac.uk/programmes/phr

Background: Mass media campaigns can be used to communicate public health messages at the population level. Although previous research has shown that they can influence health behaviours in some contexts, there have been few attempts to synthesise evidence across multiple health behaviours.

Objectives: To (1) review evidence on the effective use of mass media in six health topic areas (alcohol, diet, illicit drugs, physical activity, sexual and reproductive health and tobacco), (2) examine whether or not effectiveness varies with different target populations, (3) identify characteristics of mass media campaigns associated with effectiveness and (4) identify key research gaps.

Design: The study comprised (1) a systematic review of reviews, (2) a review of primary studies examining alcohol mass media campaigns, (3) a review of cost-effectiveness evidence and (4) a review of recent primary studies of mass media campaigns conducted in the UK. A logic model was developed to inform the reviews. Public engagement activities were conducted with policy, practitioner and academic stakeholders and with young people.

Results: The amount and strength of evidence varies across the six topics, and there was little evidence regarding diet campaigns. There was moderate evidence that mass media campaigns can reduce sedentary behaviour and influence sexual health-related behaviours and treatment-seeking behaviours (e.g. use of smoking quitlines and sexual health services). The impact on tobacco use and physical activity was mixed, there was limited evidence of impact on alcohol use and there was no impact on illicit drug behaviours. Mass media campaigns were found to increase knowledge and awareness across several topics, and to influence intentions regarding physical activity and smoking. Tobacco and illicit drug campaigns appeared to be more effective for young people and children but there was no or inconsistent evidence regarding effectiveness by sex, ethnicity or socioeconomic status. There was moderate evidence that tobacco mass media campaigns are cost-effective, but there was weak or limited evidence in other topic areas. Although there was limited evidence on characteristics associated with effectiveness, longer or greater intensity

campaigns were found to be more effective, and messages were important, with positive and negative messages and social norms messages affecting smoking behaviour. The evidence suggested that targeting messages to target audiences can be effective. There was little evidence regarding the role that theory or media channels may play in campaign effectiveness, and also limited evidence on new media.

Limitations: Statistical synthesis was not possible owing to considerable heterogeneity across reviews and studies. The focus on review-level evidence limited our ability to examine intervention characteristics in detail.

Conclusions: Overall, the evidence is mixed but suggests that (1) campaigns can reduce sedentary behaviour, improve sexual health and contribute to smoking cessation, (2) tobacco control campaigns can be cost-effective, (3) longer and more intensive campaigns are likely to be more effective and (4) message design and targeting campaigns to particular population groups can be effective.

Future work: Future work could fill evidence gaps regarding diet mass media campaigns and new-media campaigns, examine cost-effectiveness in areas other than tobacco and explore the specific contribution of mass media campaigns to multicomponent interventions and how local, regional and national campaigns can work together.

Study registration: This study is registered as PROSPERO CRD42015029205 and PROSPERO CRD42017054999.

Plain English summary

Mass media, including television, radio, social media, newspapers and other media, can be used to communicate health messages. This study reviewed the literature on media campaigns about alcohol, diet, illegal drugs, physical activity, sexual health and tobacco use. Reviews were carried out that were informed by a logic model (a framework for understanding how change can take place) of how mass media might improve health. The study aimed to provide evidence on how best to communicate public health messages through mass media. The approach and findings were discussed with members of the public and others interested in this topic.

Four literature reviews were carried out. One looked at reviews on the six health topics (review A). Another looked at single studies of alcohol campaigns as no previous review had been carried out (review B). A third focused on whether or not campaigns were value for money (review C). The fourth reviewed recent UK studies on the six topics (review D).

Mass media campaigns for public health messages can work, but the evidence is mixed. The largest amount of existing knowledge is for tobacco control campaigns, followed by sexual health and physical activity. Campaigns may not be able to directly change behaviour; however, they can improve knowledge and awareness. They can also contribute to people accessing services, like smoking quitlines or sexual health clinics. Targeting messages in campaigns to particular groups, such as children and young people, may be a good approach. Some evidence was found that tobacco control campaigns can be good value for money but little information on this was found for other topics. What makes a particular campaign work is unclear, but those that are run for longer or more often may work better. Gaps in existing knowledge remain, including the need for a future review bringing together the evidence on mass media campaigns to improve diet.

Scientific summary

Background

Mass media, such as radio, television and newspapers and digital, social and mobile media, can be used to communicate public health messages at the population level, potentially reaching many more people than other interventions. Communication through mass media involves not just the receipt of information but also a two-way interactive process in which change takes place when people choose to engage with the public health messages they receive. Health behaviours including smoking, alcohol use, poor diet and lack of physical activity are the primary preventable causes of non-communicable diseases (NCDs), including cancer, coronary heart disease and stroke. Achieving changes in these behaviours and others is an important component of NCD prevention.

Previous research has shown that mass media communications can result in positive changes in health behaviours across a range of populations. However, effectiveness varies depending on the extent, focus, targeting, theoretical basis, content, source and duration of the campaign and if and how the campaign interacts with other interventions and policies.

There have been few attempts to synthesise evidence of the effectiveness of mass media campaigns across multiple health behaviours. An approach that examines intervention effectiveness across several health topic areas is able to offer a broad overview of evidence, and to bring attention to areas in which no systematic reviews have been conducted. In addition, for those designing or commissioning mass media campaigns, reviews of the evidence can help to guide decision-making regarding in what contexts and for what behaviours mass media campaigns may be most useful.

Objectives

The aim of the study was to provide the NHS, local authorities, government and other organisations with evidence on the effective use of mass media to communicate public health messages.

The eight objectives were to:

- 1. assess the effectiveness of mass media campaigns to communicate public health messages
- 2. examine the components of messages that can be effectively communicated through mass media
- 3. explore how different types and forms of media campaigns can reach and be effective with different target populations (particularly disadvantaged groups)
- 4. assess new or emerging evidence about campaigns that employ different forms of media
- 5. examine the relationship between local, regional and national campaigns and evidence of effectiveness where this exists
- 6. assess the extent to which mass media campaigns can interact with other interventions or services to improve health outcomes
- 7. explore the currency, utility and applicability of findings as they emerge with key stakeholders
- 8. identify key research gaps in relation to mass media campaigns to communicate public health messages.

Methods

The study involved a series of reviews of existing literature on mass media for public health messages across six health topics that represent the main preventable risk factors for morbidity and mortality in

[©] Queen's Printer and Controller of HMSO 2019. This work was produced by Stead *et al.* under the terms of a commissioning contract issued by the Secretary of State for Health and Social Care. This issue may be freely reproduced for the purposes of private research and study and extracts (or indeed, the full report) may be included in professional journals provided that suitable acknowledgement is made and the reproduction is not associated with any form of advertising. Applications for commercial reproduction should be addressed to: NIHR Journals Library, National Institute for Health Research, Evaluation, Trials and Studies Coordinating Centre, Alpha House, University of Southampton Science Park, Southampton SO16 7NS, UK.

developed countries: alcohol use, diet, illicit substance use, physical activity, sexual and reproductive health and tobacco use. It involved five main elements:

- 1. development of a logic model
- 2. review of reviews (review A)
- 3. review of primary studies examining alcohol mass media campaigns (review B)
- 4. rapid review of cost-effectiveness evidence (review C)
- 5. review of recent primary studies of mass media campaigns conducted in the UK (review D).

We developed a logic model with two major components: actions (comprising the intervention inputs, activities and media outcomes) and changes (made up of proximal, intermediate and distal outcomes). We developed initial logic models for each of the topic areas before synthesising these into a common logic model. This model was then discussed with stakeholders and members of the public who helped us refine and develop it further. The resulting logic model informed the reviews by helping us to define inclusion and exclusion criteria, identify moderators and mediating factors, guide the search for evidence and to reflect on and interpret the evidence.

We searched for systematic reviews of the evidence for the effectiveness of mass media for each of the health topics covered by our study (review A). We reviewed evidence from English-language systematic reviews published between January 2000 and January 2016 on the effectiveness of mass media campaigns across these six health topics.

No systematic reviews specifically addressing alcohol use or diet met our inclusion criteria. As a result of this, we conducted a systematic review of English-language primary studies, published by July 2016, which assessed the impact of mass media campaigns to reduce alcohol consumption and related harms (review B). On diet, we conducted a scoping review of primary studies, but the volume of literature identified was extensive and beyond study time and resources. Our identification of the absence of a systematic review of mass media campaigns on diet contributed to the discussion of future research priorities.

We also conducted a rapid review of mass media cost-effectiveness evidence (review C). We reviewed systematic and non-systematic reviews, published between January 2000 and January 2017, which assessed economic studies that evaluated both the costs and benefits of mass media campaigns for any of our six health topics.

Finally, we conducted a review of English-language primary studies of mass media campaigns targeting the six health topics carried out in the UK and published between January 2011 and September 2016 (review D). This was conducted to provide additional evidence on campaign characteristics which might be associated with effectiveness and was directly relevant to the current or recent UK context.

Results

Our research aimed to address the overall aim and objectives of the study and the results are grouped into five main headings:

- 1. the effectiveness and cost-effectiveness of mass media campaigns (objective 1 and some aspects of objective 6)
- 2. the effectiveness of mass media campaigns with different target populations (objective 3)
- 3. the characteristics of mass media campaigns (objectives 2, 4 and 5)
- 4. responses of stakeholders to our findings (objective 7)
- 5. research gaps and implications for future research (objective 8).

How effective are mass media campaigns?

Review A identified 36 reviews, assessed together for the first time in our study. Overall, we found that the evidence for the effectiveness of mass media in promoting behaviour change is mixed. The amount of evidence varies across health topics, with most evidence relating to tobacco control campaigns, followed by sexual health and physical activity campaigns. No reviews examined mass media campaigns addressing alcohol or diet, although evidence on these was found in reviews examining 'mixed topics' (more than one of our six topics). The strength of evidence from reviews also varies. We found moderate evidence for the positive effects of mass media campaigns on reducing sedentary behaviour and promoting sexual health-related behaviours, such as condom use. The impact of the mass media on tobacco use and physical activity, such as stair use and brisk walking, was mixed, but with some evidence of impact in both cases. In contrast, the available and, again, low-certainty evidence on illicit drugs suggests no impact of mass media campaigns. There was very limited evidence for effects on diet.

Mass media campaigns may not be able to directly change behaviour in most instances, based on available evidence, but they can affect knowledge and awareness, which our logic model suggests may contribute to longer term outcomes. We found evidence of increased knowledge and awareness in relation to sexual health, physical activity and diet, and increased knowledge and awareness of tobacco risks and services to help quit. There were also positive impacts on intention to increase physical activity, and some evidence of positive impacts on intention to guit smoking. There was mixed evidence on intention to stop the use of illicit drugs and to use contraception.

Review A also identified 'treatment-seeking' as a reported outcome, and this is relevant to objective 6, interaction with other interventions, as it involves a mass media campaign prompting contact with services that could support behaviour change. Here we found evidence that mass media campaigns can prompt calls to smoking quitlines and may help increase the use of sexual health clinics.

Our findings suggest that the more complex the behaviour, the more difficult it may be for mass media campaigns to have an impact. Of the behaviours that were included in our review, stronger evidence of success in behaviour change was seen for sedentary behaviour and sexual health behaviour (e.g. wearing a condom). However, some included reviews suggested that mass media as part of a comprehensive approach to addressing smoking, for example, are likely to be effective and at least one found evidence that tobacco control mass media campaigns may affect attitudes towards smoking and intentions to smoke in young people.

We conducted a new systematic review of alcohol mass media campaigns, which included 24 studies (review B). This found that mass media health campaigns about alcohol are often recalled by individuals and have achieved changes in knowledge, attitudes and beliefs about alcohol, but there was little evidence of reductions in alcohol consumption.

Review C, which assessed cost-effectiveness in 20 reviews, found moderate evidence that tobacco control mass media campaigns can be cost-effective. There was weak evidence in relation to diet (restricted to salt intake) and physical activity, and no evidence in relation to the cost-effectiveness of sexual health campaigns, despite efforts to identify such evidence within the reviews.

How effective are mass media campaigns with different target populations?

The majority of the reviews included in review A provided evidence on whether the effects of mass media campaigns were similar or different across subpopulations. We found that mass media campaigns may reach and affect groups in the population differently. Although age differences were not always measured, reviews of tobacco and illicit drug campaigns found that mass media appeared to be more effective for young people and, in particular, more effective for younger children than older teenagers. There was modest evidence that mass media outcomes for tobacco, sexual health and physical activity do not differ by sex and no clear consistent evidence was found for ethnicity or socioeconomic status. When populations were categorised by baseline health behaviours, there was evidence that physical activity campaigns may be more effective for obese or less active people.

What characteristics of mass media campaigns are associated with effectiveness?

We drew on both review A and review D and our review of recent (published between 2011 and 2016) UK primary studies (23 studies) to address this question.

There was limited evidence on the contribution of mass media campaign characteristics to effectiveness, with only a small number of reviews and studies conducting statistical analyses to measure the impact of different characteristics. There was little evidence from either review regarding the role that theory or the media channel may play in campaign effectiveness. However, there was useful evidence on the duration/intensity of campaigns. Longer duration or greater intensity/exposure was found to be related to effectiveness in several reviews, with most of the evidence relating to tobacco and to a lesser extent sexual health campaigns. Although few reviews/studies specified how long or how intense campaigns should be to produce effects, one review (in the USA/Canada) suggested that advertisements should be aired for a minimum of 6 months to affect awareness and up to 24 months to have an impact on behaviours, and as frequently as possible.

There was evidence from both reviews, and particularly from recent UK studies, that the content of messages may be important, with evidence that both positive and negative messages and social norms messages can affect smoking behaviour. There was also evidence that targeting can be effective, suggesting that messages need to be tailored to target audiences while avoiding patronising or stereotyping. There was very limited evidence on new media and how they relate to effectiveness.

How did stakeholders respond to our findings?

We consulted with a range of stakeholders and the public during our study. Near the end of the study, we convened a large stakeholder event with around 50 delegates from government, local authorities, the NHS, academia and the public. Delegates who were involved in designing or implementing public health mass media campaigns expected greater and more consistent evidence of effectiveness and cost-effectiveness. Their responses were helpful in reviewing our findings. This was particularly the case for tobacco control campaigns. These have a long history and relevant questions were posed regarding the grey literature, particularly on local and regional campaigns (which our study did not assess) and the relationship between wider tobacco control policies (i.e. tax increases, smoke-free legislation and advertising bans), which the identified literature did not explore in detail. However, participants welcomed our new systematic review of mass media campaigns on alcohol and some of our key findings relating to intensity/duration and target audience.

In addition, we discussed our findings in detail with two groups of young people attending a youth club in Edinburgh. This was particularly useful in terms of reflecting on their own experiences of mass media campaigns. The young people engaged effectively with our logic model and discussed their recollection and engagement with recent public health mass media campaigns.

Research gaps and implications for future research

We identified a range of research gaps and implications for research:

- The need for a systematic review of mass media campaigns addressing diet.
- More rigorous evaluations of mass media campaigns, including detailed information on the campaign and exposure.
- More evidence on cost-effectiveness, particularly on topics other than tobacco. Researchers should aim to include cost data and ideally assess cost-effectiveness in future studies.
- More reviews and primary studies that examine digital media, including comparisons with traditional media channels. The uncontrolled and co-created nature of some new-media interventions pose particular evaluation challenges that will require the development of new methodologies.
- Better understanding of the specific contribution of mass media campaigns delivered as part of multicomponent interventions, including those seeking to influence policy agendas.
- Research to examine how local, regional and national campaigns can work together effectively.

Conclusions

This study brought together the evidence on mass media for public health messages, focusing on six of the main preventable risk factors for NCD, for the first time. Overall, the evidence is mixed but suggests that (1) campaigns can reduce sedentary behaviour and improve sexual health, (2) campaigns contribute to smoking cessation, particularly through links to wider tobacco control interventions, (3) campaigns can be cost-effective but the main available evidence is from tobacco control, (4) campaigns that run for longer and are more intensive are likely to be more effective, (5) targeting campaigns to particular population groups can be effective and (6) the messages featured in campaigns can influence outcomes. However, considerable gaps remain in the evidence, particularly regarding new-media and mass media campaigns to promote healthy diets.

Chapter 1 Introduction

Background and existing research

Behaviour change is crucial to preventing the large burden of non-communicable diseases (NCDs).^{1,2} Public health organisations recommend, and spend considerable resources on, mass media campaigns to encourage reductions in risky behaviours or adoption of healthier behaviours.^{1,3–5} Mass media campaigns can be run via traditional media channels, such as television, radio, cinema, newspapers, magazines and billboards, or via new digital media, including websites, pop-up and banner advertisements, QR (Quick Response) codes, viral marketing and social media. New media often feature an element of interactivity [e.g. liking, sharing or commenting on content and downloading campaign apps (applications)]. Campaigns aim to increase knowledge, influence attitudes and motivate target groups to change health behaviours.⁶ Because they can be delivered at the population level, they can reach large numbers of people at a relatively low cost and are widely agreed to have an important role to play in influencing health behaviour change.⁷

Evidence suggests that mass media campaigns can be effective in changing individual health behaviours, for example smoking.^{8,9} However, there have been few attempts to synthesise evidence of effectiveness across multiple behaviours. An approach that examines intervention effectiveness across several health topic areas is able to offer a broad overview of evidence, and to bring attention to areas in which no systematic reviews have been conducted.¹⁰ When evidence is scarce or highly heterogeneous (e.g. evidence of effectiveness with population subgroups), a broad overview approach allows evidence to be combined more meaningfully. For commissioners, it can help to guide decision-making regarding in what contexts and for what behaviours mass media campaigns may be most useful.

Aim and objectives

The aim of this research was to provide the NHS, local authorities, government and other organisations with evidence on the effective use of mass media to communicate public health messages.

In order to do so, we aimed to systematically review the evidence of effective uses of mass media campaigns to convey messages that lead to health behaviour change in the target audience – by preventing risky or unhealthy behaviours, by encouraging the cessation of existing risky or unhealthy behaviours, by promoting the uptake of healthy behaviours or by raising awareness of key public health issues.

In addition to the overall aim, the study had the following objectives:

- 1. Assess the effectiveness of mass media campaigns to communicate public health messages.
- 2. Examine the components of messages that can be effectively communicated through mass media.
- 3. Explore how different types and forms of media campaigns can reach and be effective with different target populations (particularly disadvantaged groups).
- 4. Assess new or emerging evidence about campaigns that employ different forms of media (including new media).
- 5. Examine the relationship between local, regional and national campaigns and evidence of effectiveness where this exists.
- 6. Assess the extent to which mass media campaigns can interact with other interventions or services to improve health outcomes.
- 7. Explore the currency, utility and applicability of findings with key stakeholders.
- 8. Identify key research gaps in relation to mass media campaigns to communicate public health messages.

Most, but not all, of our objectives were addressed in this study. The first reason for not addressing all of the objectives was that our reviews did not identify evidence to address them. This was the case for objective 4, for which we found very limited evidence on new media, and, to some extent, for objective 5, for which some key findings about campaigns of different scope and scale were available but not enough information applicable to the UK context of local, regional or national was identified. The second reason was that it became apparent that some avenues for exploration were beyond the time and resources available for the study when the volume of literature had been initially assessed. This was the case for objective 6, as it emerged that trying to fully address this objective would have required reviewing a very sizeable body of additional literature in which mass media was just one element of much broader multicomponent interventions. These limitations are discussed in *Chapter 7*.

Overview of the study

The study comprised a series of evidence reviews informed by a logic model. We have been guided in the write-up of this report by the Preferred Reporting Items for Systematic Reviews and Meta-Analyses (PRISMA) statement,¹¹ although, as this report documents a large review of reviews combined with syntheses of primary studies, we had to develop our own structure to some extent.

Review of reviews

Reviews of reviews are becoming an established component in the repertoire of evidence-informed policy and practice.^{12–14} They allow key findings from a range of studies to be easily accessed, while also identifying research gaps. We reviewed and synthesised evidence from English-language systematic reviews published between January 2000 and January 2016 on the effectiveness of mass media campaigns across six health topics that represent the main preventable risk factors for disease morbidity and mortality in developed countries:¹⁵ alcohol use, illicit substance use, diet, physical activity, sexual and reproductive health and tobacco use. We registered this review of reviews (review A) with PROSPERO (CRD42013004170)¹⁶ (see *Chapters 2* and *5*).

Reviews of primary studies

No systematic reviews addressing alcohol use or diet met our inclusion criteria for the review of reviews described in the previous section. As a result of this, and as anticipated in our protocol,¹⁶ we conducted two reviews of primary studies. The first (review B), a systematic review of English-language primary studies (published by July 2016), was conducted to assess the effectiveness of mass media public health campaigns to reduce alcohol consumption and related harms. Studies examining drink driving mass media interventions and college campus campaigns were excluded. We registered this review with PROSPERO (CRD42017054999)¹⁷ (see *Chapter 3*).

The second (review D) was a systematic review of English-language primary studies of mass media campaigns targeting the same six health topics, conducted in the UK and published between January 2011 and September 2016. The focus of the review was on evidence concerning the characteristics of UK mass media campaigns associated with effectiveness, rather than on the effectiveness of those campaigns per se (see *Chapter 5*).

Other reviews

We conducted a rapid review of reviews describing the cost-effectiveness of mass media campaigns (review C). We reviewed reviews and systematic reviews, published between January 2000 and January 2017, which assessed economic studies that evaluated both the costs and benefits of mass media campaigns for any of our six health topics of interest (see *Chapter 4*).

As described previously, no systematic reviews addressing diet met our inclusion criteria for the review of reviews. A scoping search for English-language primary studies (published by August 2016) was conducted for studies of mass media public health campaigns aiming to improve dietary behaviours. The modified

search strategy (diet terms and mass media terms) was tested in one database (MEDLINE) and identified > 16,500 hits. A full review and synthesis was too great to conduct within the time and resources of the current project. Project resources were instead directed towards the review of recent UK primary studies (published between January 2011 and September 2016), referred to previously (review D). We focused on UK studies to complement the review of reviews (review A) and enhance the relevance for UK practitioners, policy-makers and commissioners (see *Chapter 5*).

The logic model

The utility of logic models in systematic reviews

In a broad systematic review such as this, a range of different types of interventions in different contexts are compared and contrasted. Critical to this process is an understanding of how the different interventions are thought (or intended) to work; this provides a conceptual framework to structure the analysis. Based on the idea of programme theory from the evaluation literature, this framework is often described as a 'logic model', which is a diagrammatic representation of the key intervention inputs, the activities undertaken in the intervention, and the causal pathway that is triggered by the intervention, resulting in the desired (or not desired) outcome(s).¹⁸ Thinking critically about the causal pathway is important in public health interventions, as there are often long chains of outcomes between the intervention and the ultimate health outcome. For example, in this review, a given mass media campaign might be designed to have a given message to raise awareness about the consequences of a given behaviour. It may adopt a given strategy or intervention theory in order to raise awareness, but merely raising awareness does not necessarily result in improved health. The raised awareness needs to result in a decision to change behaviour; the initial behaviour change, and, ultimately, sustained healthier behaviours, may lead to an improvement in population health.

Many systematic reviews develop a logic model a priori, as this can then drive many of the decisions that need to be made during the systematic review process. First, systematic reviewers need to make consistent decisions about which studies are in the scope of the review and which are not. The logic model can be used to develop inclusion/exclusion criteria in order to delineate the scope of the review. Once the studies for the review have been identified, the logic model can be used to determine what data need to be extracted about studies in a standardised way, in order to structure the comparative analysis. The logic model then helps to structure the analysis, enabling reviewers to identify commonalities and differences in interventions that may help to explain variance between their results. However, although the existence of an a priori logic model can be useful for these reasons, it should be considered provisional and subject to change once the studies have been examined. This is important because once reviewers have seen the range of studies in their review they may find that the logic model does not contain sufficient nuance to capture significant differences in intervention approach, content or in the contextual factors that might influence intervention implementation - or the long causal chain between intervention and health outcome. For this reason, this review contains two logic models: the first, which informed the early stages of the review, helped reviewers to determine what was relevant and irrelevant, and what data should be extracted; the second is based on the first, and also summarised the reviewers' understanding of the research contained within the review.

Development of the initial logic model for mass media interventions

The initial logic model owes much of its overarching structure to the work of Chen.¹⁹ We split the model into two major components: the action model (comprising the intervention inputs, activities and media outcomes) and the change model (made up of proximal, intermediate and distal outcomes). Although this may appear to be rather linear, and not cognisant of relevant theorising about complex interventions (e.g. feedback loops, phase changes and emergent outcomes; see Rogers²⁰), we consider mass media interventions as operating in different ways to other public health interventions, and it is possible to conceptualise the intervention as a coherent entity that is implemented, and then the outcomes that result from it in a linear way (i.e. there may be feedback loops and other manifestations of complexity within the

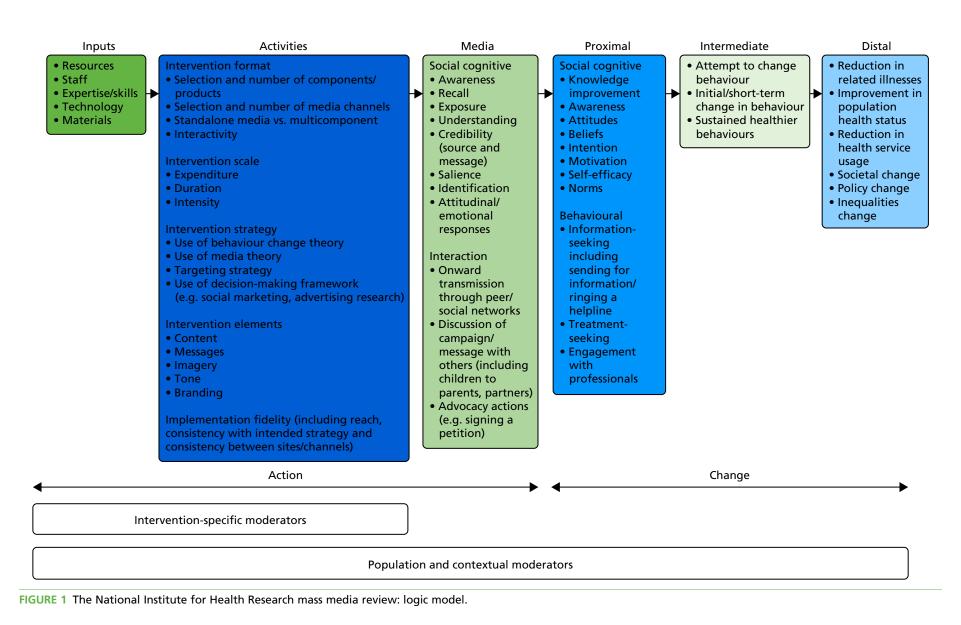

change model, but these can be understood as operating downstream of the mass media intervention, and not interacting with it).

We first developed our initial logic model for mass media interventions separately for each of the public health areas of the review before synthesising these into a common logic model. As well as demonstrating how mass media interventions may work, the resulting logic model was used to guide the evidence synthesis through helping to define inclusion and exclusion criteria, identifying moderators (and potentially subgroup analyses if meta-analyses had been possible at a later stage), and identifying mediating factors and guiding the search for evidence.²¹ Our initial model represents a synthesis of logic models developed independently of mass media interventions of smoking cessation and mass media interventions of healthy eating/physical activity. In common with the development of logic models more broadly, both logic models were developed through working backwards across an outcome and action chain starting from the distal outcome.

Beginning with smoking cessation, we first located the small number of systematic reviews of mass media interventions for smoking that included a logic model, and used the model included in the review by Niederdeppe et al.²² as a starting point. This included detail on the change part of a logic model in particular, but was enhanced with further details that helped to disaggregate some of the intermediate outcomes around behaviour change; this corresponded with other models of 'stages of change' in health promotion. The action part of the model was enhanced through examining logic models that were developed in other studies of mass media interventions of public health but that were not necessarily specific to smoking cessation (e.g. Huhman et al.²³), as well as significant components that were identified in reviews of mass media smoking interventions, but that were not conceptualised in a logic model (e.g. Durkin et al.²⁴). Finally, further stages of change of smoking cessation were identified through examining the logic models that were included in reviews of public health and policy interventions for smoking cessation, but that did not necessarily involve mass media.²⁵ A similar process was employed to develop the logic model for healthy eating/physical activity. To synthesise the models, common components were identified and the language harmonised; for example, both the physical activity and smoking cessation logic models included common stages of change around the attempts at adopting healthier behaviours and reduction in unhealthy behaviours as precursors to successful behaviour change, although these were originally expressed in language specific to each health topic. Even though the two health topics included here were chosen because they were conceptually relatively different and could affect very different populations (making them suitable candidates to pilot this approach), their synthesis was relatively straightforward as both involved synthesising logic models of mass media interventions to stimulate behavioural change for lifestyle behaviours. However, as we expected that some of the health topics that the review would consider may be more complex, we expected that our process of synthesising logic models and developing an overall logic model might result in topic-specific pathways being depicted within the final model; for example, mass media interventions for some health topics might also attempt to change behaviour through an intermediary party, and this might need to be depicted in the logic model. Thus, our initial logic model is presented here (Figure 1), and it was continually challenged and refined throughout the process of the review.

Public and stakeholder engagement

Members of the public and stakeholders from a range of organisations were involved in this study. In particular, public and stakeholder engagement informed the development of the research, our refinement of research plans and the interpretation of findings. Stakeholder engagement was particularly important in shaping the focus and scale of our literature searches, in developing and finalising our logic model, and in supporting the research team to reflect on the implications and key messages from our findings, including for the design of mass media campaigns and future research. *Chapter 6* describes our engagement activities in more detail.

PUBLIC HEALTH RESEARCH 2019 VOL. 7 NO. 8

Chapter 2 What is the impact of mass media campaigns on behaviour and other outcomes? Findings from the review of reviews (review A)

Overview

This chapter reports evidence from the review of reviews on the impact of mass media campaigns on behavioural and other outcomes, and examines evidence of variations in impact between different target populations. The chapter addresses two of the study objectives:

assess the effectiveness of mass media campaigns to communicate public health messages
 explore how different types and forms of media campaigns can reach and be effective with different target populations (particularly disadvantaged groups).

Methods

Overviews of reviews are becoming an established component in the repertoire of evidence-informed (or evidence-based) policy and practice.^{12–14} In order to fulfil the above objectives, we conducted a review of reviews and carried out a high-level synthesis of the evidence on the effects of mass media campaigns across multiple health behaviours. We registered this review with PROSPERO (reference number CRD42013004170).¹⁶

Identification of reviews

We combined terms concerning mass media campaigns, such as media, 'mass communication', 'social marketing' and broadcast, with terms denoting systematic reviews and meta-analyses (see *Appendix 1*). We searched the Database of Promoting Health Effectiveness Reviews, the Cochrane Database of Systematic Reviews, the Database of Abstracts of Reviews of Effects, the Campbell Collaboration Library of Systematic Reviews, the Health Technology Assessment database hosted by the Centre for Reviews and Dissemination, EMBASE, PubMed, the Cumulative Index to Nursing and Allied Health Literature, MEDLINE and Web of Science between 10 December 2015 and 5 January 2016. We did not systematically search the grey literature, which was a departure from our protocol; however, systematic reviews published as reports, rather than in peer-reviewed journals, were still identified by the strategy described above. To check the quality of the searches, we searched the results to find systematic reviews already known to the team. The reference lists of any relevant reviews of reviews were also searched. Results were uploaded to an Evidence for Policy and Practice Information and Co-ordinating Centre (EPPI)-Reviewer 4 database and deduplicated (*Figure 2*).²⁶

Review selection

Records were screened against the inclusion criteria listed in *Box 1*. Reviews were screened on title and abstract by three reviewers. We carried out comparison coding as an inter-rater reliability test, and, when we agreed on the included and excluded reviews at a 90% rate, the reviewers continued individually. Full-text reviews were then retrieved, and individual expert teams assessed the papers in the different health topic categories to reach the final list of reviews. Two researchers from the wider team adjudicated if there was uncertainty about whether or not to include a review. See *Appendix 2* for a list of reviews excluded by full-text assessment.

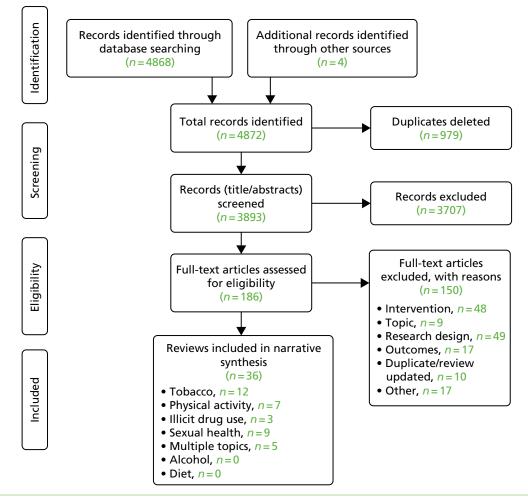

FIGURE 2 The PRISMA flow diagram of the identification and selection of reviews (review A).

BOX 1 Inclusion criteria (review A)

The review:

- Was published in or after 2000.
- Was published in English.
- Concerned human populations.
- Included interventions that met the definition of a mass media intervention the intentional use of any media channel(s) of communication by local, regional and national organisations to influence lifestyle behaviour through largely passive or incidental exposure to media campaigns, rather than largely dependent on active help-seeking (adapted from Wakefield *et al.*⁶ and Bala *et al.*²⁷). This excludes, for example, health campaign websites that individuals actively searched for or signed up for.
- Examined one or more of the following health topics alcohol use, illicit substance use, diet, physical
 activity (including sedentary behaviour), sexual and reproductive health, and tobacco use. Reviews
 examining mass media interventions promoting health screening behaviours (e.g. human immunodeficiency
 virus testing and cervical screening) are excluded because NHS population screenings are not part of the
 remit of the National Institute for Health Research Public Health Research programme.
- Was conducted as a systematic review, which was defined as including a specified search strategy from more than one database, an assessment of the quality of studies and some kind of synthesis of the primary studies.
- Reported sufficient outcome data on behaviour change and/or its individual determinants. In multicomponent interventions, the outcome data had to relate to the mass media component, not to the whole intervention.

Data extraction

Data from reviews identified as meeting the inclusion criteria were extracted into a standardised data extraction form. Data extracted included review characteristics, participant characteristics, types of study design, types of synthesis and outcome data (particularly social cognitive and behavioural outcomes). For each topic, one reviewer extracted the data, and a sample ($\geq 25\%$) was checked by a second reviewer to ensure the consistency of the extraction.

Quality appraisal and relevance assessment

We used the Risk Of Bias In Systematic reviews (ROBIS) tool to assess the risk of bias of included systematic reviews.²⁸ Included reviews were assessed by one researcher, and a second researcher checked all their assessments against the full-text review and ROBIS guidelines, with any disagreements discussed between the two researchers. We rated the relevance of the included reviews to our aims (high or low relevance), based on two dimensions: its relevance to an Organisation for Economic Co-operation and Development (OECD) context (included studies conducted in OECD countries versus all studies in the review that were conducted in non-OECD countries)²⁹ and whether or not the review's main focus was on mass media interventions. We also extracted information on the quality of the included studies in each review as assessed by the review authors: good, medium or low quality or not stated.

Data synthesis

Given the highly heterogeneous nature of the interventions and reviews, we did not attempt to conduct meta-analysis, and a narrative synthesis approach was pursued.³⁰ We initially tabulated all available data according to topic and tried to identify duplicate results. We then created tabular summaries of the full data, with information on potential bias within the included evidence base retained. We investigated patterns in the available results, making comparisons across topics, outcomes and population subgroups [based on the PROGRESS (Place of residence; Race/ethnicity/culture/language; Occupation; Gender/sex; Religion; Education; Socioeconomic status; Social capital) characteristics],³¹ with due attention paid to contradictory data. Analysis proceeded iteratively, with the whole team regularly meeting to discuss findings. To summarise the results for the outcomes of interest (behaviours, intentions, awareness/knowledge and attitudes), a symbol was applied to indicate how good the evidence was for a positive or negative effect.³² This incorporated the risk of bias of the relevant reviews and reported effect sizes/directions. Inconsistency statistics were extracted from relevant meta-analyses.

To make conclusions based on the available evidence, we developed a systematic and transparent approach, building on principles of the Grading of Recommendations, Assessment, Development and Evaluation (GRADE) approach.^{33,34} In addition to risk of bias, we also assessed the domains of inconsistency, indirectness and imprecision for each behaviour. Inconsistency assessed whether or not the reported effects for a behaviour differed between assessments of behaviour change and its determinants, as well as whether or not high statistical heterogeneity was observed within meta-analysis. Directness referred to how directly the evidence related to the health topics examined in this review within the UK context. Evidence on behavioural outcomes was considered 'direct' whereas evidence regarding awareness/knowledge, attitudes or intentions only was considered 'indirect'. Similarly, if available evidence was primarily drawn from non-OECD countries then this was considered indirect. Imprecision was assessed on the basis of the precision of the effect estimate [e.g. did the 95% confidence interval (CI) exclude no effect?]. 'Overall effect' was assessed by taking into account the direction of effect for behaviour with consideration of the indirect outcomes and the risk of bias in the evidence available. When there was evidence at a low risk of bias that was directly observed for the behaviour of interest, with little imprecision and inconsistency, we considered this to have a high level of certainty. We downgraded to moderate, low or very low certainty if there was a high risk of bias (by two levels), indirect evidence (by two levels), inconsistency (by one level) and imprecision (by one level).

Overview of the included reviews

Thirty-six systematic reviews were included from the initial 3893 records screened (see Figure 2). The reviews examined mass media interventions for tobacco use (12 reviews),27,35-45 sexual health (nine reviews),46-54 physical activity (seven reviews, 55-61 of which one focused on reducing sedentary behaviour)55 and illicit drug use (three reviews),^{62–64} with five reviews addressing 'mixed topics'^{65–69} (i.e. more than one of our six health topics) (Table 1). Although no systematic reviews met our inclusion criteria for alcohol use or diet mass media interventions, studies evaluating campaigns targeting alcohol or diet were included in four mixed heath topics reviews. Fourteen reviews were assessed to have a high risk of bias and 22 were considered to have a low risk of bias (see Appendix 3). Approximately half of the reviews focused solely on mass media interventions (n = 17), and the others reviewed broader ranges of behaviour change interventions including mass media campaigns. When geographical data were provided for mass media studies, 15 of the reviews included at least one study from the UK and four reviews included studies from only non-OECD countries (all sexual health topic reviews); the rest were mainly studies of mass media campaigns from OECD countries. On the basis of the focus of the reviews on mass media and geographical data, 18 of the included reviews were judged as highly relevant to the topic. We searched for reviews published between January 2000 and January 2016; the time period covered by the included reviews' searches ranged from database inception to January 2015, and the most recent included study was published in 2013.

The reviews focused on a range of target groups, including studies of mass media campaigns targeting by age group, socioeconomic status, ethnicity, sex, sexual orientation, addictive behaviours, morbidity or parental/pregnancy status, in addition to whole-population, untargeted campaigns. Twelve reviews did not report the sample sizes of their included studies, and a further four reviews only reported some samples sizes. Over the other 20 reviews, the sample sizes of included studies ranged from 27 to 130,245 participants.

Most of the reviews included studies of mass media campaigns that had national reach (n = 22), with a third of these including only national campaigns (n = 7); the rest also included regional and local campaigns. Ten reviews included studies of mass media campaigns that had a local reach only or had a local or national reach. Four of the reviews did not report details on the reach of the campaigns.

Twenty-six reviews presented a narrative synthesis of study results, six reviews completed a meta-analysis of the data and four reviews used both methods to synthesise and present findings. The reviews examined a range of direct behavioural outcomes (reducing harmful behaviours, increasing healthy behaviours and help-seeking), indirect behavioural outcomes and sociocognitive outcomes (intentions, awareness and knowledge, attitudes and beliefs, and norms and self-efficacy), and 16 reviews analysed data for subpopulations (see *Table 1*).

The types of studies included by the reviews in their syntheses were reported in most of the reviews (n = 34). The majority of syntheses included a mixture of study designs, from randomised control trials (RCTs) and trials, cohort studies, pre–post studies and post-test only studies (n = 23). Four reviews synthesised data from RCTs and trials only, six reported data from pre–post-test studies only and one review reported post-test data only (see *Appendix 4* for the detailed characteristics of the included systematic reviews).

Evidence of impact on behavioural outcomes

We examined evidence of the effects of mass media campaigns on behavioural outcomes relating to all of our health topics. Rather than present evidence simply by health topic, we synthesised evidence across three broad categories of behavioural outcome: reducing harmful behaviours, increasing healthy behaviours and treatment-seeking. We were interested in examining whether or not the effectiveness of

TABLE 1 Summary of included reviews (review A)

Review (first author and year); risk of bias (ROBIS)	Health topic	Was mass media the sole focus?	Aim of the review	Relevance to our review of reviews	Type of synthesis	Number of included studies	Number o relevant studies
Abioye (2013);55 low risk of bias	Physical activity	Yes	We searched six electronic databases from their inception to August 2012 and selected prospective studies that evaluated the effect of MMCs on physical activity in adults	High	Meta-analysis	9	9
Bala (2013); ²⁷ low risk of bias	Tobacco use	Yes	To assess the effectiveness of MMCs in reducing smoking among adults. Four research questions: i) Do MMCs reduce smoking (prevalence, cigarette consumption, quit attempts and quit rates) compared with no intervention in comparison communities? ii) Do MMCs run in conjunction with tobacco control programmes reduce smoking, compared with no intervention or with tobacco control programmes alone? iii) Which study characteristics relate to their efficacy? iv) Do tobacco MMCs cause any adverse effects?	High	Narrative synthesis	11	11
Bertrand (2006); ⁴⁶ low risk of bias	Sexual health	Yes	To review the strength of the evidence for the effects of three types of [broadcast] mass media interventions on HIV/AIDS-related behaviour among young people in developing countries and to assess whether these interventions reach the threshold of evidence needed to recommend widespread implementation	Low	Narrative synthesis	15	15
Brinn (2010);³⁵ low risk of bias	Tobacco use	Yes	To determine the strength of the evidence that mass media interventions to prevent smoking in young people may: 1) reduce smoking uptake among youths (< 25 years), 2) improve smoking attitudes, behaviour and knowledge, 3) improve self-efficacy/self-esteem, 4) improve perceptions about smoking including the choice to follow positive role models	High	Narrative synthesis	7	7
Brown (2012); ⁵⁶ high risk of bias	Physical activity	Yes	The goal of the systematic review described in this summary was to determine the effectiveness of stand-alone MMCs to increase physical activity at the population level	High	Meta-analysis and narrative synthesis	16	16

TABLE 1 Summary of included reviews (review A) (continued)

Review (first author and year); risk of bias (ROBIS)	Health topic	Was mass media the sole focus?	Aim of the review	Relevance to our review of reviews	Type of synthesis	Number of included studies	Number of relevant studies
Brown (2014); ³⁷ high risk of bias	Tobacco use	No	To assess the effectiveness of population-level interventions/ policies to reduce socioeconomic inequalities in smoking among adults by assessing primary studies of any intervention/policy that reported differential effects on a smoking-related outcome in at least two socioeconomic groups	Low	Narrative synthesis	117	30
Brown (2014); ³⁶ high risk of bias	Tobacco use	No	What is the equity impact of interventions/policies to reduce youth smoking?	Low	Narrative synthesis	38	1
Byrne (2005); ⁶⁵ high risk of bias	Multiple – alcohol use, tobacco use, illicit drug use	Yes	Aims to critically review the literature on past and current drug, alcohol, and tobacco use prevention media campaigns, examining the similarities across health communication programme believed to be effective, with the aim of viewing their applicability for the prevention of youth problem gambling	High	Narrative synthesis	25	25
Carter (2015); ⁴⁷ low risk of bias	Sexual health	No	Community education may involve activities that seek to raise awareness and promote behaviour change, using mass media, social media, and other media or interpersonal methods in community settings. This systematic review evaluated the evidence of the effects of community education on select short- and medium-term family planning outcomes	High	Narrative synthesis	17	14
de Kleijn (2015); ³⁸ high risk of bias	Tobacco use	No	The primary aim of this review was to determine how effective school-based interventions are in preventing girls smoking, and the secondary objective was to determine which interventions are most successful	Low	Meta-analysis and narrative synthesis	37	4
Derzon (2002);56 high risk of bias	Multiple – alcohol use, tobacco use, illicit drug use	Yes	A synthesis into the capability of media interventions to reduce youth substance-use	High	Meta-analysis	72	72

Review (first author and year); risk of bias (ROBIS)	Health topic	Was mass media the sole focus?	Aim of the review	Relevance to our review of reviews	Type of synthesis	Number of included studies	Number of relevant studies
Ellis (2003); ⁶⁷ low risk of bias	Topics: multiple – diet, tobacco use	No	(1) to provide an overview of the cancer control interventions (adult smoking cessation, adult healthy diet, mammography, cervical cancer screening, control of cancer pain) that are effective in promoting behaviour change and (2) to identify evidence-based strategies that have been evaluated to disseminate these cancer control interventions	Low	Narrative synthesis	31	8
Ferri (2013); ⁶² low risk of bias	Illicit drug use	Yes	To assess the effectiveness of mass media campaigns in preventing or reducing the use of or intention to use illicit drugs among young people	Low	Meta-analysis and narrative synthesis	23	23
Finlay (2005); ⁵⁷ high risk of bias	Physical activity	Yes	The 1998–2002 studies (interventions) were reviewed for their success in impacting message recall and behaviour change. The newer studies plus those identified by Kahn et al. (2002) and Marcus et al. (1998), were assessed for the presence of a more sophisticated understanding of the media processes of inception, transmission and reception	High	Narrative synthesis	17	8
French (2014); ⁴⁸ low risk of bias	Sexual health	Yes	An exploratory review was conducted to assess research examining awareness, acceptability, effects on HIV testing, disclosure and sexual risk, and cost-effectiveness of HIV mass media campaigns targeting MSM	High	Narrative synthesis	12	12
Gould (2013); ³⁹ low risk of bias	Tobacco use	Yes	(a) To systematically review and summarise the literature describing attitudes and key responses to culturally targeted anti-tobacco messages [in indigenous and First Nations populations in Australia, New Zealand, USA and Canada] and (b) identify any differences in effect according to whether the messages were addressed to the target population or general population	Low	Narrative synthesis	20	11
Grilli (2000); ⁴⁹ low risk of bias	Sexual health	Yes	To assess the effects of mass media on the utilisation of health services	Low	Narrative synthesis	21	2

TABLE 1 Summary of included reviews (review A) (continued)

Review (first author and year); risk of bias (ROBIS)	Health topic	Was mass media the sole focus?	Aim of the review	Relevance to our review of reviews	Type of synthesis	Number of included studies	Number of relevant studies
Guillaumier (2012); ⁴⁰ low risk of bias	Tobacco use	Yes	1. Systematically review the published evidence of the effectiveness of MMCs (with the primary purpose of encouraging smokers to quit) with smokers from socially disadvantaged groups. 2. Critique the methodological quality of the evidence for the effectiveness of MMCs with disadvantaged groups	High	Narrative synthesis	17	17
Hemsing (2012); ⁴¹ high risk of bias	Tobacco use	No	1. Do interventions that involve partners' support of their pregnant partners lead to effective smoking cessation among pregnant partners during pregnancy and postpartum? 2. Are there interventions that are effective in encouraging partners who smoke to stop smoking? Do the intensity and modality of the intervention influence effectiveness?	Low	Narrative synthesis	9	1
Hill (2014); ⁴² high risk of bias	Tobacco use	No	To review and synthesise existing evidence on the equity impact of tobacco control interventions by SES	Low	Narrative synthesis	77	12
Jepson (2006); ⁴³ low risk of bias	Tobacco use	Yes	To synthesise evidence evaluating the effectiveness of mass media interventions on helping people to quit smoking/ tobacco use and/or to prevent relapse. These interventions were considered for both the effectiveness of the channel of communication and also for the effectiveness of message content	High	Narrative synthesis	44	39
Kahn (2002);58 high risk of bias	Physical activity	No	The Guide to Community Preventive Service's methods for systematic reviews were used to evaluate the effectiveness of various approaches to increasing physical activity: informational, behavioural and social, and environmental and policy approaches. Changes in physical activity behaviour and aerobic capacity were used to assess effectiveness	Low	Narrative synthesis	94	6
Kesterton (2010);⁵⁰ high risk of bias	Sexual health	No	This review investigates the effectiveness of interventions aimed at generating demand for and use of sexual and reproductive health services by young people, and interventions aimed at generating wider community support for their use	Low	Narrative synthesis	74	3

Sexual health	Yes	This meta-analysis was conducted to synthesize evaluations of mass media–delivered HIV prevention interventions, assess the effectiveness of interventions in improving	Low	Meta-analysis	54	54
		condom use and HIV-related knowledge, and identify moderators of effectiveness				J 4
Physical activity	Yes	To assess progress and quality of (i) campaign evaluation design and sampling, (ii) use of theory and formative research in campaign development and (iii) evidence of campaign effects including proximal, intermediate and behavioural outcomes	High	Narrative synthesis	18	18
Physical activity	No	To review selected and recent environmental and policy interventions designed to increase physical activity and improve nutrition as a way to reduce the risk of heart disease and stroke, promote CVH [cardiovascular health], and summarise recommendations	Low	Narrative synthesis	64	7
Multiple – diet, physical activity, tobacco use	No	To identify and assess the evidence for the effectiveness of population approaches in changing dietary, physical activity, or tobacco use habits and related health outcomes. Population strategies were media and educational campaigns consumer information economic incentives, school and workplace approaches, local environmental changes and direct restrictions	Low	Narrative synthesis	≈100 (not stated)	31
Physical activity	No	To conduct a systematic review of the best available evidence across all relevant disciplines to determine what characterises interventions effective in promoting walking; who walks more and by how much as a result of effective interventions; and the effects of such interventions on overall physical activity and health	Low	Narrative synthesis	48	2
l∨ pl tc	1ultiple – diet, hysical activity, obacco use	1ultiple – diet, No hysical activity, obacco use	behavioural outcomeshysical activityNoTo review selected and recent environmental and policy interventions designed to increase physical activity and improve nutrition as a way to reduce the risk of heart disease and stroke, promote CVH [cardiovascular health], and summarise recommendationsAultiple – diet, hysical activity, obacco useNoTo identify and assess the evidence for the effectiveness of population approaches in changing dietary, physical activity, or tobacco use habits and related health outcomes. Applications for commercial reproduction should be addressed to: NHR Journals library, National Institute for Health Research, Evaluation, Trials and Studies Coordinating Centre, Alpha House, University of Southampton Science Park, Southampton SO16 7NS, UK.

mass media campaigns differs across these three types of behavioural outcome; for example, are mass media campaigns more effective at encouraging or reinforcing positive behaviours than at discouraging negative behaviours? We defined 'reducing harmful behaviours' as bringing about a reduction in behaviours that have harmful effects (e.g. preventing young people from taking up smoking or encouraging smoking cessation, reducing other substance use and reducing sedentary behaviour). We defined 'increasing healthy behaviours' as encouraging greater engagement in behaviours that are protective of health, such as engaging in physical activity or using a condom. 'Treatment-seeking' was defined as engaging in specific actions to secure information, advice, support or treatment relating to the health topics examined in the review, for example using a sexual health service, seeking testing for sexually transmitted diseases or calling a smoking quitline.

Reducing harmful behaviours

Fourteen reviews reported evidence on whether or not mass media campaigns reduced harmful behaviours, as outlined in *Table 2.*^{27,35,38,40,41,43–45,55,62,63,65,66,68} Eleven focused on a specific health topic and three examined mixed health topics.^{65,66,68} All 14 reviews included studies based in OECD countries, and seven included studies conducted in the UK.^{27,41,43–45,55,68} Ten of the reviews were rated as having a low risk of bias^{27,35,38,40,43–45,55,62,68} and four were considered to have a high risk of bias.^{41,63,65,66} Eleven reviews focused on a specific health topic and three examined mixed health topics.^{65,66,68} Three reviews used meta-analysis, ^{55,62,66} with the remainder presenting results in a narrative synthesis.

Effects on sedentary behaviour were examined in one review. A meta-analysis of studies based in OECD countries on the effect of mass media campaigns on physical activity in adults found evidence of mass media campaigns reducing sedentary behaviour [relative risk (RR) 1.15, 95% CI 1.03 to 1.30], with moderate heterogeneity observed ($l^2 = 63\%$; p = 0.018).⁵⁵

Two reviews reported on whether or not mass media campaigns had an impact on illicit drug use. A meta-analysis of RCT studies of campaigns targeting young people (aged < 26 years) found no effect (standardised mean difference –0.02, 95% CI –0.15 to 0.12), but did find evidence of reductions in the use of illicit drugs in an analysis of non-RCT studies.⁶² The other, a review of the effects of anti-illicit drug public service announcements on youth (no definition by age specified) found very small positive reductions in illicit drug use, with considerable inconsistency; however, it should be noted that this review had a high risk of bias.⁶³

Nine reviews (eight specifically focusing on tobacco^{27,35,38,40,41,43–45} and one examining a range of health topics⁶⁸) examined the impact of mass media campaigns on tobacco use. All included OECD-based studies and five included UK studies.^{27,41,43–45} Four reviews, all considered to have a low risk of bias, examined the impact on preventing smoking uptake in young people. The review by Richardson *et al.*,⁴⁴ which included one UK study, reported positive results for smoking prevention: the narrative synthesis found evidence to suggest that mass media campaigns can prevent the uptake of smoking in young people (evidence from one review and two studies) and that industry-sponsored studies are less effective (evidence from one study). The other three reviews – Wilson *et al.*⁴⁵ (which included one UK study), de Kleijn *et al.*³⁸ and Brinn *et al.*³⁵ – all reported mixed results.

Five reviews examined smoking cessation or quit rates. Four reviews with a low risk of bias that included UK or OECD studies reported mixed results.^{27,40,43,45} The fifth review reported no effect on quit attempts; the review had a high risk of bias and the evidence was from one study conducted in the UK.⁴¹ Finally, a review that examined a range of health topics reported evidence of mass media campaigns having a positive effect on the combined outcomes of smoking prevention and cessation.⁶⁸

The impact of mass media on the use of a combination of substances (alcohol, illicit drugs and alcohol) was examined by two mixed health topic reviews.^{65,66} Although both of these reviews reported positive effects, both reviews were rated as having a high risk of bias.

TABLE 2 Summary of reducing harmful behaviours (including reducing sedentary behaviour, illicit drug use, smoking prevalence and alcohol use) (continued)

20

Increasing healthy behaviours

Twelve reviews reported evidence on whether or not mass media campaigns can increase healthy behaviours (*Table 3*). Ten focused on specific health topics (either physical activity^{55–61} or sexual health^{52–54}) and two examined a range of topics.^{68,69} None of the included reviews focused exclusively on diet/healthy eating, but one of the mixed-topic reviews included evidence on diet-related behaviours.⁶⁹ Nine of the reviews included studies conducted in OECD countries,^{55–61,68,69} four included studies conducted in the UK^{55,57,58,60} and two did not report the countries.^{53,56} Two of the reviews, focusing on sexual health interventions, comprised studies conducted in low- and middle-income countries.^{52,54}

Eight of the reviews examined whether or not there was evidence that mass media campaigns could increase physical activity. A range of physical activity outcomes were reported, including walking, overall levels of physical activity, and using the stairs. In reviews that examined impact on stair use, the mass media campaigns typically comprised 'point-of-decision prompts', such as posters in locations with high footfall (e.g. public transport hubs and workplaces), encouraging people to use the stairs rather than the lift or escalator.

Two reviews with a low risk of bias reported evidence that mass media campaigns increased walking behaviour. In a meta-analysis of four studies, Abioye *et al.*⁵⁵ found evidence that mass media campaigns could produce an increase in brisk walking (RR 1.53, CI 1.25 to 1.87), whereas Ogilvie *et al.*⁶¹ found evidence from two studies that mass media campaigns increased the time spent walking. Two reviews with a low risk of bias, one focusing specifically on physical activity⁶⁰ and one examining a range of topics,⁶⁸ found that stair use was increased by mass media campaigns comprising point-of-decision prompts (e.g. signs and banners to encourage using stairs). A third review, with a high risk of bias, also reported evidence that mass media campaigns could increase stair use.⁵⁸

However, reviews that examined overall levels of physical activity or time spent in physical activity reported generally mixed evidence. A meta-analysis of four studies in one review with a low risk of bias found no clear impact on overall physical activity (RR 1.02, 95% CI 0.91 to 1.14; P = 72%).⁵⁵ In contrast, a mixed-topic review at low risk of bias found a positive effect on increases in overall physical activity.⁶⁸ The evidence from three reviews with a high risk of bias that examined changes in physical activity behaviours was generally mixed.^{56,57,59}

Four reviews provided evidence on whether or not mass media campaigns could increase healthy sexual health behaviours. Three reviews with a low risk of bias examined the impact of mass media on condom use: two of these reviews conducted meta-analysis and found that media campaigns had a positive effect on condom use, with inconsistency in the effect estimates [odds ratio (OR) 1.39, 95% CI –1.06 to –1.83;⁵³ and OR 2.01, 95% CI 1.42 to 2.84, OR 2.10, 95% CI 1.51 to 2.91⁵⁴]. The third review, which was of mixed health behaviour topics, also reported positive effects on condom use.⁶⁹ The fourth review reported mixed results of the effect of mass media on sexual health behaviours;⁵² this review was found to have a high risk of bias.

Finally, a mixed-topic review with a low risk of bias reported that mass media campaigns could have a positive effect on the consumption of healthy food.⁶⁸

Treatment-seeking

Ten reviews provided information on treatment-seeking: six focused on treatment-seeking in relation to sexual health^{46–50.52} and four focused on treatment-seeking in relation to tobacco use (*Table 4*).^{27,37,42,43} Seven of the reviews included studies conducted in OECD countries,^{27,37,42,43,47–49} and all seven included studies conducted in the UK. Six were at a low risk of bias^{27,43,46–49} and four were at a high risk of bias.^{37,42,50,52}

NIHR Journals Library www.journalslibrary.nihr.ac.uk

Of four reviews examining the impact of media campaigns on the use of sexual health services or clinics, one found a positive effect⁴⁷ and one reported mixed results.⁴⁹ Positive results were reported in two further reviews,^{50,52} but results were from only one study in each review and both reviews were at high risk of bias. The effects of mass media campaigns on the uptake of HIV testing or HIV services was examined in two reviews with a low risk of bias, both reporting mixed evidence.^{46,48}

There was evidence of mass media campaigns having a positive effect on calls to smoking quitlines from two reviews with a low risk of bias,^{27,43} although this was based on only one study in one of the reviews.²⁷ Mixed evidence was reported for the impact of mass media campaigns on smoking quitlines in two reviews with a high risk of bias.^{37,42}

Evidence of the impact on indirect behavioural outcomes and social cognitive outcomes

We also examined evidence of the effects of mass media campaigns on indirect behavioural outcomes and social cognitive outcomes. Indirect behavioural outcomes were defined as intentions to engage in, reduce or desist from unhealthy behaviours (such as smoking) or to engage in healthy behaviours (such as condom use). Social cognitive outcomes comprised awareness, knowledge, attitudes, beliefs, norms and self-efficacy.

Intentions

Seven reviews examined whether or not there was evidence that mass media campaigns had an impact on intentions to change behaviour (*Table 5*).^{35,39,47,59,62,63,69} All of the reviews included studies from OECD countries but none included studies from the UK. Statistical methods were used in two reviews to assess the impact of mass media campaigns on illicit drug use intentions.^{62,63} The remaining five reviews used narrative synthesis. Most of the reviews were of good quality (at a low risk of bias).

Three reviews with a low risk of bias examined tobacco use: two focused solely on tobacco^{35,39} and one mixed-topic review included tobacco.⁶⁹ Positive results for intentions to quit or to smoke were reported in two of the reviews,^{39,69} whereas one review that focused on reducing smoking prevalence in young people reported largely mixed results for the intention to start smoking.³⁵ The quality of the included studies was assessed by the reviews themselves as medium to low.

Statistical pooling in two reviews, one at low risk of bias⁶² and one at high risk of bias,⁶³ found a mixed impact of mass media campaigns on illicit drug use intentions (including not to use, to reduce use or to stop use), with no clear indication of either a positive or negative overall effect.

One sexual health review with a low risk of bias reported largely mixed results for intentions to use contraception,⁴⁷ whereas a physical activity review reported largely positive results for intentions to be more active,⁵⁹ but the review had a high risk of bias.

Awareness and knowledge

Fifteen reviews reported on whether or not mass media campaigns had an impact on awareness and knowledge (*Table 6*).^{27,35,39,44,46,47,50–52,57,62,65–68} The reviews had varying levels of relevance to the UK context: three reviews included non-OECD country research only, five reviews included one or two UK studies and the rest were reviews of studies from mainly OECD countries. Two reviews presented statistical results, with the remaining reviews presenting only narrative results.^{51,66}

NIHR Journals Library www.journalslibrary.nihr.ac.uk

There was evidence that mass media campaigns increased knowledge and awareness in relation to sexual health (including knowledge of HIV prevention and transmission, contraception and services). One low-risk-of-bias meta-analysis of 54 studies found consistent positive results for the improvement in knowledge of HIV transmission (d+=0.30, 95% CI 0.18 to 0.41, based on 47 reports) and prevention (d+=0.39, 95% CI 0.25 to 0.52, based on 65 reports).⁵¹ Positive results regarding sexual health awareness and knowledge outcomes were also reported in four reviews using narrative synthesis,^{46,47,50,52} but three of these^{46,50,52} did not include any studies from the UK or other OECD countries, one review had a high risk of bias,⁵² and both Speizer *et al.*⁵² and Kesterton and Cabral de Mello⁵⁰ based their results on only one study. The review by Bertrand and Anhang⁴⁶ also reported some mixed results.

Four reviews with a low risk of bias found mixed evidence that mass media campaigns could improve awareness and knowledge regarding tobacco. Two reviews, which both included studies from the UK,^{27,44} reported mixed results, whereas the third review reported positive results³⁹ and the fourth review reported negative results.³⁵ A mixed-topic review with a low risk of bias that examined the effects on knowledge of smoking cessation helplines reported positive results.⁶⁷

The effects on knowledge of illicit drugs were examined in one illicit drugs review with a low risk of bias, which reported mixed results.⁶² In addition, two mixed-topic reviews^{65,66} examined the effects on tobacco, alcohol and illicit drugs knowledge. A meta-analysis of the effects on drugs knowledge reported positive results [$\Delta = 0.05$ standard deviation (SD); p < 0.05]⁶⁶ and a narrative review also reported positive results;⁶⁵ however, both of these reviews had a high risk of bias.

There was weak evidence that mass media campaigns could have an impact on awareness and knowledge regarding physical activity. Overall positive results, including from UK studies, were reported in one mixed-topic review with a low risk of bias that examined this outcome,⁶⁸ whereas positive results were also reported by Finlay and Faulkner,⁵⁷ but the review had a high risk of bias.

Finally, two of the mixed-topic reviews examined evidence of the impact on diet-related awareness and knowledge, both reporting positive results;^{67,68} the review by Mozaffarian *et al.*⁶⁸ included UK studies.

Attitudes, beliefs, norms and self-efficacy

Ten reviews reported on whether or not mass media campaigns had an impact on attitudes, beliefs, norms and self-efficacy (*Table 7*).^{27,35,44,46,47,52,62,65,66,68} One review conducted a meta-analysis;⁶⁶ however, only narrative results were presented in the other nine reviews. Most of the reviews were of good quality (low risk of bias), but their relevance to the UK varied.

For illicit drugs, the evidence was mixed. A mixed-topic meta-analysis that examined effects on drug use attitudes reported overall positive results ($\Delta = 0.02$ SD; p < 0.05),⁶⁶ but the review was at high risk of bias, whereas mixed evidence of impact on attitudes to illicit drug use and perceived peer norms was reported in a review with a low risk of bias⁶² and in a review with a high risk of bias.⁶⁵

For sexual health, overall positive results regarding beliefs about risk of pregnancy were reported in one review with a low risk of bias.⁴⁷ Positive results regarding other attitude changes were reported in two other sexual health reviews,^{47,52} but Speizer *et al.*⁵² included only low-income countries and in both cases the reported results were from only one study. Mixed results were reported for the impact on self-efficacy, and negative results were reported for the impact on beliefs by Bertrand and Anhang,⁴⁶ but this review was limited to low-income country studies and, therefore, it is of less relevance.

The evidence was mixed for tobacco. Three reviews, two including UK studies, reported overall mixed results for the impact on attitudes,^{27,35,44} and Brinn *et al.*³⁵ also reported overall negative results for the impact on self-efficacy.³⁵ However, a mixed-topic review including UK studies that examined the impact on attitudes to smoking reported overall positive results.⁶⁸ The same review also reported overall positive results for attitudes to physical activity.

Evidence of the impact on distal outcomes

In addition to investigating the impact of mass media on proximal outcomes (such as beliefs, attitudes and self-efficacy) and intermediate outcomes (including attempted and sustained behaviour change), evidence on distal outcomes was sought. As noted in the logic model (see *Figure 1*), this included reduction in illnesses, improved population health, reduced health service usage, societal change, policy change and impact on inequalities. Of all of the systematic reviews included, only one reported on any distal outcomes.⁴³ The authors noted that:

There is evidence of good quality (1&2 +, C), which shows an effect of mass media interventions on attitudes towards smoking and intentions to smoke among young people under 25 years.
 © National Institute for Health and Care Excellence (NICE) 2008. A Review of the Effectiveness of Mass Media Interventions Which Both Encourage Quit Attempts and Reinforce Current and Recent Attempts to Quit Smoking.⁴³ Available from www.nice.org.uk/guidance/ph10/evidence/a-review-of-the-effectiveness-of-mass-media-interventions-which-both-encourage-quit-attempts-and-reinforce-current-and-recent-attempts-to-quit-smoking-pdf-369842079. All rights reserved. Subject to Notice of rights. NICE guidance is prepared for the National Health Service in England. All NICE guidance is subject to regular review and may be updated or withdrawn. NICE accepts no responsibility for the use of its content in this product/publication

This suggests that mass media programmes may have contributed to the denormalisation of smoking among young people.

Evidence of the impact on different target subpopulations

Summary of the approach to subpopulations in reviews

The majority of the included reviews provide evidence about whether or not the effects of mass media campaigns were comparable across one or more subpopulations. Reviews differ in the extent to which the identification and synthesis of subpopulation differences formed a primary objective. In several reviews, all focusing on tobacco control campaigns, the main aim was to determine the equity or inequity of effects of campaigns across socioeconomic groups.^{37,40,42} Some reviews dedicated part of their synthesis to looking at effects in specific subgroups,^{43–45,54,62} or to looking more generally for factors that moderate sizes of effect^{51,55} or described results separately for subgroups when this was shown in the original papers.^{27,58,61,63} Most reviews provide a narrative synthesis of results for different subpopulations as described by the original studies; very few have conducted a formal statistical subgroup analysis. Some reviews that have included a meta-analysis have examined the factors that cause heterogeneity in study findings,^{51,55} or analyse in subgroups when available from the original studies.^{54,62} A few reviews simply highlighted the subgroups in which statistically significant effects had been found in the original studies; if this was not part of a more formal subgroup analysis, these results have not been included.

When reviews focused on effects of mass media campaigns in a particular target population, those effects have been described earlier according to the relevant outcomes.

The majority of reviews concentrated on behaviour change outcomes, either reducing harmful behaviour or increasing health behaviour, rather than proximal outcomes, when describing and synthesising effects in subpopulations.

Description of the subpopulations that have been considered

The subpopulations considered differ markedly according to health behaviour, with sex^{27,43,44,51,54,55,58} and age^{27,44,45,51,55,62} being the only common factors across a number of reviews in different areas. Differences have also been examined according to ethnicity for several health behaviours.^{27,39,44,58} Consideration of socioeconomic factors and the equity of effect across socioeconomic groups has been exclusively a feature of reviews of the tobacco control literature, in line with the strong socioeconomic differential in the pattern of smoking and smoking-related morbidity in many developed countries.^{27,37,40,42,44} Other subpopulations have been defined according to the pre-campaign level of behaviour, for example by the level of initial physical activity or obesity for campaigns aimed at improving physical activity,^{58,61} by prior sexual health behaviour for a review of campaigns relating to sexual health,⁵¹ and a review of campaigns relating to illicit drugs examined effects according to sensation-seeking behaviour.⁶³

Effects by subpopulations

Effects by age

Differences by age were reported in terms of youth versus adults, and according to differing age groups of children and adults. For some health behaviours, notably smoking, reviews focused exclusively on youth (smoking uptake) or adults (smoking cessation) and the findings and any contrasting findings of these reviews are described in *Reducing harmful behaviours*. Six reviews, all at low risk of bias, describe effects by age group: three for tobacco control campaigns,^{27,44,45} one for illicit drugs,⁶² one for physical activity⁵⁵ and one for sexual health.⁵¹ The age groups considered varied markedly between behaviours and between reviews.

Two reviews with a low risk of bias provided evidence that the effects of tobacco control mass media campaigns differ by age, and may be greater for younger children than for older children and greater for youths than for adults. The evidence is relevant to the UK as the reviews concerned included studies only from the UK or OECD countries. The review by Richardson *et al.*⁴⁴ found evidence that tobacco control campaigns appeared to benefit (i.e. decrease intentions to smoke, initiation rates or continuation of smoking) younger children more than older children. Wilson *et al.*⁴⁵ report that findings for youth populations were more consistent than those for adults, with most studies reporting a reduction of 20–40% in the odds of smoking initiation. However, a third low-risk-of-bias review of tobacco mass media campaigns found that the impact of age was contradictory, with three campaigns detecting positive effects among older smokers, and three detecting positive effects among younger smokers (aged up to 34 years).²⁷

For illicit drugs, Ferri *et al.*⁶² found that campaigns on methamphetamine use affected past-year prevalence only in 12- to 17-year-olds, not in 18- to 24-year-olds.

In relation to other behaviours, the evidence was less consistent. A metaregression of campaigns targeting physical activity found that age was an important determinant of heterogeneity in relation to reducing sedentary behaviour, with stronger effects in older age groups (p = 0.054); each additional 10 years was associated with a 27% greater reduction in sedentary behaviour (p = 0.054).⁵⁵ However, age was not a significant determinant of heterogeneity in relation to improving overall physical activity. For sexual health mass media campaigns, LaCroix *et al.*⁵¹ found that age was not a predictor of effect size for campaigns.

Effects by sex

Seven reviews describe effects by sex: three for tobacco control campaigns,^{27,43,44} one for physical activity⁵⁵ and two for sexual health.^{51,54}

There was evidence in metaregression that sex was not an important determinant of heterogeneity for physical activity mass media campaigns, for either reducing sedentary behaviour or increasing activity.⁵⁵

[©] Queen's Printer and Controller of HMSO 2019. This work was produced by Stead *et al.* under the terms of a commissioning contract issued by the Secretary of State for Health and Social Care. This issue may be freely reproduced for the purposes of private research and study and extracts (or indeed, the full report) may be included in professional journals provided that suitable acknowledgement is made and the reproduction is not associated with any form of advertising. Applications for commercial reproduction should be addressed to: NIHR Journals Library, National Institute for Health Research, Evaluation, Trials and Studies Coordinating Centre, Alpha House, University of Southampton Science Park, Southampton SO16 7NS, UK.

For campaigns on sexual health, there was evidence suggesting slightly greater impact on condom use by females than by males in one review with results stratified by sex; the odds of having used a condom during the most recent sexual encounter were only slightly different, at 1.7% (95% CI 1.1% to 2.7%) higher for males and 2.2% (95% CI 0.5% to 8.7%) higher for females who had been exposed to condom social marketing.⁵⁴ However, another review of sexual health mass media campaigns found that no sample characteristics, including sex, were significant predictors of effect size magnitude for any outcome of interest.⁵¹

Two tobacco reviews found that the impact of sex was inconclusive, with some studies showing positive long-term effects for men and some for women.^{27,44} One study in the review by Bala *et al*.²⁷ found significant differences in intervention quit rates for women but not for men, compared with controls. A third tobacco review reported that few of the included studies evaluated the differential effectiveness in subgroups of the sample but found modest evidence that campaigns were more effective for women than for men only in relation to quit and win and community campaigns.⁴³

Effects by ethnicity

Four reviews described effects by some marker of ethnicity: three were tobacco control reviews^{27,39,44} and one focused on physical activity.⁵⁸ Guillaumier *et al.*⁴⁰ also refer to ethnicity but use this to identify populations of deprivation, and these results are therefore presented in the section on socioeconomic differences (see *Effects by socioeconomic group*).

Evidence regarding media campaign effectiveness and ethnicity was generally inconsistent, inconclusive and mixed. Two reviews of tobacco mass media campaigns observed no consistent or conclusive relationship between campaign effectiveness and ethnicity.^{27,44} One review examined the effect of generic media on indigenous people compared with the general population,³⁹ and found weak evidence that generic tobacco control messages devised for the whole population can be as effective in terms of recall for indigenous populations as for the general population; however, this may not translate into quit rates.

In a review of physical activity campaigns, Kahn *et al.*⁵⁸ included two studies that reported results separately for black people and found mixed evidence: one study showed a decline in the percentage of black people using the stairs when the sign contained a generic message; however, a message specifically designed for a black population was effective in increasing the percentage of stair users.

Effects by socioeconomic group

Five reviews, all focusing on tobacco mass media campaigns, described differential effects by socioeconomic group.^{27,37,40,42,44} For four of these reviews,^{37,40,42,44} the main aim was to compare the effectiveness of campaigns across socioeconomic groups or to consider effectiveness specifically within deprived populations. Overall, the evidence suggested that tobacco control campaigns have had inconsistent socioeconomic equity effects. However, there is a lack of good-quality studies looking at the differential effects of mass media campaigns, especially those aimed at behaviours other than smoking.

In the review by Brown *et al.*,³⁷ 12 studies examined the equity impact of mass media campaigns promoting the use of quitlines and/or nicotine replacement therapy (NRT) (i.e. whether or not results differed by socioeconomic status). Five studies were positive (i.e. the campaigns reduced inequality), three were neutral (there was no difference in impact by socioeconomic status) and three were negative (the campaigns were found to increase inequality and one was unclear regarding equity impact). Similarly, of 18 studies examining the equity impact on quitting, three showed a positive equity impact, two were neutral, five were negative (including four Quit & Win competitions), two were mixed and six were unclear.³⁷

The review by Hill *et al.*⁴² found evidence that mass media campaigns generated greater awareness of quitlines among less educated smokers, with three out of four US studies that evaluated campaigns promoting local quitlines finding higher awareness among less educated smokers.

Other reviews of tobacco mass media campaigns found no consistent relationship between campaign effectiveness and educational status²⁷ or socioeconomic status.⁴⁰ Guillaumier *et al.*⁴⁰ reported results from several studies, finding an inconsistent pattern overall. Two studies in the review examined measures of campaign exposure and found that campaigns were either less likely or equally likely to be recalled by disadvantaged groups than by more advantaged smokers. Four studies looked at campaign perceptions: three found no differences in the perceived effectiveness of campaigns regardless of sociodemographic group, and a fourth found that Indigenous Australians perceived a variety of television advertisements as more effective than did non-Indigenous Australians. Motivational responses of smokers (calling quitlines, promoting quit attempts and quit intentions) were assessed in five studies, with mixed results. Four studies assessed the effectiveness of campaigns in promoting cessation: three campaigns were equally effective and one campaign was more effective in reducing smoking rates in disadvantaged smokers than in more advantaged smokers. This review considered the methodological quality of these studies and its main conclusion was that there is poor methodological rigour in research into the effectiveness of mass media campaigns among socially disadvantaged groups.⁴⁰

Richardson *et al.*⁴⁴ reported that there was a lack of information regarding the impact of the socioeconomic status of children and young people on the effectiveness of mass media campaigns.

Effects by pre-campaign measures of behaviour

Two reviews, both of physical activity campaigns, defined subpopulations by their pre-campaign level of physical activity or obesity,^{58,61} and one review of sexual health campaigns defined subpopulations in accordance with pre-campaign sexual activity and use of condoms.⁵¹ One further review focusing on campaigns relating to illicit drug use examined effects according to individuals' sensation-seeking behaviour.⁶³

Two physical activity reviews noted evidence of stronger effects in populations who were classified as obese at baseline (Kahn *et al.*⁵⁸) or sedentary at baseline (Ogilvie *et al.*⁶¹), although the evidence was weak overall, as the review by Kahn *et al.*⁵⁸ was at high risk of bias, and in the Ogilvie *et al.*⁶¹ review the findings related to only two mass media studies in a review with a wider focus. Kahn *et al.*⁵⁸ found that posters encouraging stair use were effective in both those classified as obese and those not classified as obese, but the median net increase in the percentage of people taking the stairs was higher among the obese group.⁵⁸ Ogilvie *et al.*,⁶¹ examining the two mass media studies in the review, reported that significant net increases in self-reported time spent walking were observed only in the most sedentary subgroup within the study population.⁶¹ Neither prior level of sexual activity nor pre-campaign rate of condom use were significant predictors of effect size magnitude for any outcome of interest in a sexual health review.⁵¹ An illicit drug use review suggested possible stronger effects in a RCT for a subgroup assessed as having a high level of sensation-seeking behaviour, but with no formal synthesis.⁶³

Overall strength of the evidence

Table 8 presents the findings for our overall summary of findings for the effects of mass media on health behaviours. This overall rating summarises review findings, drawing on the principles of the GRADE approach.^{33,34} In particular, we considered the risk of bias of included systematic reviews, potential inconsistency in the results, the extent to which the evidence base reflects behaviour change within a UK context and imprecision in the effect estimates.

Although our approach is inspired by GRADE,^{33,34} it has been modified substantially as straightforward implementation is challenging and would have resulted in all assessments being characterised as having very low certainty. This would not have allowed the differing levels of certainty to be communicated. However, it is worth noting that these assessments are not comparable to other GRADE Summary of Findings tables.

 ∇ , negative results, no statistics reported/narrative results.

•, no effect, statistics provided.

O; no effect, no statistics reported/narrative results.

◀▶, mixed results, statistics provided.

, mixed results, or statistics reported/narrative results.
 , no evidence identified for this outcome.

With regard to our certainty in mass media campaigns in achieving a positive impact on public health, we conclude that there is:

- low-certainty evidence for positive effects on improving sexual health behaviour, with existing reviews synthesising evidence that is primarily derived from low-income settings
- very low-certainty evidence of healthier behaviours in relation to diet and substance use
- low-certainty evidence for no effect on increased physical activity and reduced use of illicit drugs
- low-certainty evidence for the effect on tobacco being mixed
- a large amount of variation in effectiveness across the evidence, suggesting that factors related to the intervention and context are crucial determinants of effectiveness
- an absence of evidence about the impact on alcohol consumption.

Summary

This review of systematic reviews published between January 2000 and January 2016 brings together the evidence base on the impact of mass media campaigns on health behaviours (including alcohol use, illicit substance use, diet, physical activity, sexual and reproductive health and smoking cessation and prevention) for the first time. Overall, the evidence base for the effectiveness of mass media in promoting behaviour change is mixed. The amount of literature varies. Of the 36 reviews that met our inclusion criteria, the most commonly studied behaviour was tobacco use, followed by sexual health and physical activity. Just three reviews of media campaigns on the use of illicit drugs were identified. A further five systematic reviews looked at campaigns addressing more than one behaviour, of which only four included content on alcohol and/or diet. However, no single review examining the effectiveness of using mass media to address alcohol use or diet was found, identifying an important gap in the literature. The strength of evidence from reviews also varies. Using a modified GRADE approach,^{33,34} we found moderate evidence for the positive effects of mass media campaigns on reducing sedentary behaviour and sexual health. Low-certainty evidence for positive impacts on diet was found, although the overall volume of evidence on diet was very limited. The impact of mass media campaigns on tobacco use and physical activity was mixed, but with low-certainty evidence in both cases. In contrast, the available and, again, low-certainty evidence on illicit drugs use suggests no impact of mass media. All reviews found considerable variation between individual studies as described in a meta-analysis or narrative synthesis, suggesting that variations in implementation of the campaign and evaluation methods may be important.

For treatment-seeking, there was low-certainty evidence that mass media campaigns can help increase the use of sexual health clinics or services. Whether or not media campaigns can prompt calls to telephone quitlines for smoking cessation has been fairly extensively studied in five reviews. Overall, the direction of effect looks positive, with campaigns serving to prompt calls to quitlines, but variation in results and the quality of studies was identified; therefore, there is only moderate certainty in the strength of this finding.

Mass media campaigns may reach and affect groups in the population differently. Although age differences were not always measured, reviews of tobacco and illicit drug campaigns found that mass media appeared to be more effective for young people and particularly for younger children than for older teenagers. There was modest evidence that mass media outcomes for tobacco, sexual health and physical activity do not differ by sex and no clear consistent evidence was found for ethnicity or socioeconomic status. Looking at baseline measures of health behaviours, physical activity campaigns may be more effective for the less active or for obese people than for others.

Chapter 3 What is the impact of mass media campaigns on alcohol-related behaviour and other outcomes? Findings from the review of primary studies of alcohol campaigns (review B)

This systematic review of primary studies of alcohol campaigns (review B) has been published in full by Young *et al.*⁷⁰ This is an Open Access article distributed in accordance with the terms of the Creative Commons Attribution (CC BY 4.0) license, which permits others to distribute, remix, adapt and build upon this work, for commercial use, provided the original work is properly cited. See: http://creativecommons. org/licenses/by/4.0/. The text in this chapter includes minor additions and formatting changes to the original text. The paper and the supplementary files (including the exclusion criteria and a sample search strategy) are available at https://doi.org/10.1093/alcalc/agx094 (accessed 30 April 2018). In this chapter, we present a scientific summary of the review.

Background

There are approximately 8800 alcohol-related deaths annually in the UK⁷¹ and consumption of alcohol is causally linked with > 60 medical conditions including seven types of cancer.⁷² In England, 7% of adults regularly consume more than current low-risk guidelines⁷³ and there are an estimated 1.1 million alcohol-related hospital admissions each year.⁷⁴ There is a need for effective population-level strategies to reduce consumption and prevent related harm.

Review A highlighted a lack of review-level evidence of the effectiveness of mass media in addressing alcohol use. Two reviews included some evidence on alcohol as part of wider reviews of multiple behaviours;^{65,66} however, no single comprehensive review was identified that examined the impact of mass media on alcohol consumption and related outcomes.

Other reviews have shown that mass media campaigns can reduce drink driving in some circumstances^{10,75} although alcohol campaigns may not be effective in school or college campus environments.^{76,77} Other than these topics, evaluations of alcohol-related mass media campaigns have not been comprehensively synthesised in a way that can inform current policy.

Objective

The objective was to conduct a systematic review of evidence of the effectiveness of mass media public health campaigns to reduce alcohol consumption and related harms.

Methods

The review protocol¹⁷ was registered with PROSPERO (reference number CRD42017054999) and this systematic review (review B) has been published in full.⁷⁰ Eligibility criteria are given in *Box 2*.

Eight bibliographic databases were searched from the date of inception to July 2016: MEDLINE, EMBASE, PubMed, The Cochrane Library, Web of Science, Scopus, Applied Social Sciences Index and Abstracts and Education Resources Information Center (ERIC). Each unique search result was screened for relevance by one of a team of four reviewers. Full-text reports of eligible references were assessed for eligibility by one

BOX 2 Eligibility criteria (review B)

Inclusion criteria

Studies of campaigns with the characteristics

- Purposeful use of mass media channels to influence health behaviours and the individual-level determinants of health behaviours.
- Mass media channels included television, radio, cinema, online broadcasting, newspapers and magazines, leaflets/booklets, direct mail, outdoor advertising, e-mail and digital media.
- Aimed at reducing alcohol consumption and its determinants.
- Multicomponent interventions if they assessed the specific effects of a mass media component.

Types of studies

- Primary research studies.
- Any study design.
- Reported in English.
- Any country.
- Reported at least one of the following outcomes alcohol consumption, alcohol-related social cognitive variables (e.g. knowledge, intentions and social norms), media exposure outcomes (e.g. campaign awareness, exposure and understanding), alcohol-related harm and health service usage.

Exclusion criteria

Studies of campaigns with the characteristics

- Involved individual person-to-person delivery.
- Required active engagement before receipt of the message rather than passive message exposure.
- Used a baseline measure to tailor or target a subsequent mass media message.
- Targeted drink driving.
- Promoted alcohol consumption.
- Based in schools.
- Targeted college students within university campuses.
- Social norms campaigns in which it was not evident from the information available that a mass media channel was used.

Types of studies

- Campaign message testing.
- Evaluations of alcohol advertisement bans.
- Evaluations of warning labels on alcohol products.
- Evaluations of online treatment or self-help programmes.

reviewer and random samples were checked by a second reviewer. The references of included studies were examined for any further potentially relevant studies.

Data were extracted from included studies, with outcomes informed by the project logic model, and a sample were double-extracted by a second reviewer. Studies were assessed for quality using the Effective Public Health Practice Project (EPHPP) Quality Assessment Tool for Quantitative Studies,⁷⁸ with all assessments checked by a second reviewer. Owing to study heterogeneity, a narrative synthesis was conducted, first on behaviour change outcomes and then on behavioural determinants, including social cognitive and campaign exposure outcomes.

Results

There were 10,212 unique search results, 170 of which were assessed for eligibility as a full-text report (*Figure 3*). Twenty-nine papers were included in the review. They reported 24 different studies that had a range of designs (11 controlled longitudinal and 13 uncontrolled or cross-sectional) and countries (eight in the USA, five in Australia, two in Finland, two in New Zealand, two in the UK, one in Canada, one in Denmark, one in Italy, one in the Netherlands and one in Sri Lanka). Television and/or radio were used in 18 studies. Other media channels that were used were posters, newspapers, pamphlets, e-mails and online video. On EPHPP study quality ratings, two were strong,^{79,80} four were moderate^{81–84} and 18 were weak.^{85–102} The most common reasons for a weak rating were not reporting reliability and validity of data collection tools, a high risk of selection bias and a weak study design.

Alcohol consumption

There was little evidence of reductions in alcohol consumption associated with exposure to campaigns based on 13 studies reporting this outcome.^{79-82,84,88,91-93,95,97,100,102} Six of these studies compared exposed and non-exposed groups, or exposed groups over time; five reported no statistically significant differences in consumption.^{79,81,82,84,95} One study found that participants in a group exposed to a television and mailed letter campaign decreased their consumption on a typical day by 47%, contrasting with increases in the groups receiving either the television or letter components or neither.⁸⁸ Other studies examined associations between campaign viewing or awareness and consumption: one reported that increases in awareness in older adolescence, but not younger adolescence, was associated with decreases in binge drinking,⁸⁰ one reported that campaign viewing significantly predicted drinks consumed¹⁰² and two found no significant difference in consumption.^{91,97}

Treatment- and information-seeking

There was some evidence, from four weak-quality studies, that campaigns generated increases in treatment-seeking or information-seeking.^{85,87,92,97} For example, referrals for alcoholism were reported to have increased by 65% following a campaign.⁹⁷

Intentions and motivation

Three studies reported intentions to reduce alcohol consumption. In one study, those who reported that they had seen a campaign reported an increase in intentions to decrease alcohol use whereas others decreased their intentions.¹⁰² Another study found an increase in the proportion of people reporting that they were likely to reduce their consumption from pre test to post test.⁹¹ In the other study, the impact of the campaign on intentions was not well described.⁸⁴ In a single study reporting motivation to reduce consumption, half of drinkers recognising the campaign reported that it made them feel either very or somewhat motivated to reduce their consumption.⁹¹

Beliefs and attitudes

Five studies reported alcohol-related beliefs or attitudes with mixed findings.^{81,84,88,90,97} For example, one study reported an increase in support for some policies aimed at limiting consumption but not for others.⁸¹

Knowledge

There was evidence that alcohol-related knowledge increased, based on eight studies. These included knowledge of unit consumption guidelines,^{91,92} cancer risk,⁹¹ the risks of alcohol use during pregnancy,^{83,89,93} sources of support for problem drinkers⁹⁷ and general knowledge about alcohol.^{84,96} For example, there was a significant improvement in knowledge of the risks of alcohol use during pregnancy in an exposed group compared with a control group.⁸³

Other outcomes

Other studies reported self-efficacy,^{79,96} social norms,¹⁰² campaign interaction or discussion,^{82,83,86,98,99} recall or recognition of campaigns^{82,83,85,88,89,91,92,94,95,97–100} and attitudinal or emotional responses.^{79,92} The evidence was strongest for recall, with the proportions of people remembering campaigns or their messages being generally high.

Discussion

Findings from this review of primary studies published by July 2016 suggest that mass media campaigns have not reduced alcohol consumption, although most did not state that they directly aimed to do so and the evidence is limited by mostly weak study designs and self-reported outcomes. Campaigns can be recalled and increase knowledge, especially in areas where knowledge was initially low (e.g. unit consumption guidelines or cancer risk), suggesting that they can have an impact on important precursors to behaviour change. However, alcohol marketing and pro-alcohol cultural norms create a challenging environment in which alcohol health promotion campaigns must operate.

Conclusion

Mass media public health campaigns about alcohol can often be recalled by individuals, and are associated with changes in knowledge, attitudes and beliefs about alcohol. There is little evidence that campaigns reduced alcohol consumption but most studies did not report consumption as an outcome. Mass media can, however, have an impact on outcomes that could lead to support for other public health actions to reduce alcohol consumption and harm.

Chapter 4 What is the cost-effectiveness of mass media campaigns? Evidence from the cost-effectiveness review (review C)

Background

Mass media campaigns have high upfront costs, and evidence of effectiveness is not sufficient to conclude that they offer value for money. However, the wide reach of mass media campaigns means that they have the potential to offer significant benefits at a low cost per head. The cost-effectiveness of mass media campaigns is an essential consideration for policy-makers.

Methods

We conducted a rapid review of reviews of the cost-effectiveness of mass media campaigns.

Literature searches for reviews of economic evaluations

We combined relevant reviews identified in the original search (see *Chapter 2*) with additional reviews and systematic reviews identified using a literature search that specifically sought to identify reviews of economic evaluations published between January 2000 and January 2017. We conducted a rapid literature search using Web of Science and Google Scholar. The search strategy is summarised in *Appendix 5*.

Inclusion and exclusion criteria

We included reviews or systematic reviews describing the cost-effectiveness of paid mass media interventions (including multicomponent interventions in which a major component was mass media) for the relevant health topics. The cost-effectiveness findings had to be described in a results section, even if the findings were that there were no relevant studies. Included reviews were required to assess economic studies that evaluated both costs and benefits of mass media campaigns (i.e. full economic evaluations, not just intervention costs or cost savings). Systematic reviews were defined as those including both a systematic literature search and quality assessment of included papers.

We excluded reviews of reviews and papers that assessed industry-funded mass media campaigns.

Results

Following abstract screening, we screened the full texts of 11 reviews identified in the original searches and a further 29 studies that were identified in the new search. Following full-text screening, we included 20 reviews.

Synthesis of findings

Of the 20 reviews that met the inclusion criteria, 13 were systematic reviews^{27,35,48,61,103–111} and seven were non-systematic reviews.^{24,112–117} The characteristics of the reviews are summarised in *Tables* 9 and 10.

Eight reviews were on the topic of smoking,^{24,27,35,104,110,111,113,114} four were on sexual health,^{48,103,107,109} two were on physical activity^{61,106} and two were on diet.^{116,117} Four reviews covered multiple behaviours.^{105,108,112,115}

CEA, cost-effectiveness analysis; CUA, cost-utility analysis; MMC, mass media campaign; N/A, not applicable.

Four of the included reviews had mass media campaigns as the sole focus and reviewing economic evaluations as a specific aim of the review.^{48,104,105,111} Four of the reviews had mass media campaigns as the sole focus but did not have reviewing economic evaluations as a specific aim of the review.^{24,27,35,109} Ten of the included reviews did not have mass media campaigns as the sole focus but did have reviewing economic evaluations as a specific aim of the review did not have mass media campaigns as the sole focus but did have reviewing economic evaluations as a specific aim of the review.^{103,106–108,110,112,113,115–117} Two of the reviews did not have mass media campaigns as the sole focus or reviewing economic evaluations as a specific aim of the review, but reported on economic evaluations in the results section of the review.^{61,114}

Eight of the included reviews included no relevant studies.^{24,27,48,61,103,105,107,109} Nine reviews included one or two relevant studies.^{35,106,108,110,113–117} Three reviews included three or more relevant studies, with a maximum of 11.^{104,111,112} Of these, two reviews were on the topic of smoking^{104,111} and one was a mixed-topic review but all of the relevant included studies were on smoking.¹¹²

A total of 15 individual primary studies were reported in the reviews. The characteristics of the primary studies are summarised in *Table 11*, based on the information extracted from the reviews. Eleven primary studies were on smoking,^{118–128} two were on physical activity^{129,130} and two were on diet.^{131,132} The majority of the primary studies were from the UK and the USA.

Taken together, the reviews and the findings of the primary studies within the reviews provide moderate evidence that tobacco control mass media campaigns can be cost-effective. There is weak evidence in relation to diet (although this is restricted to reductions in salt intake) and physical activity. There is no evidence in relation to the cost-effectiveness of sexual health campaigns, despite efforts to identify such evidence in systematic reviews.

Summary

From our rapid review of reviews (published between January 2000 and January 2017) of the cost-effectiveness of mass media campaigns, evidence on cost-effectiveness was extremely limited for all health topics except smoking. The finding that there is moderate evidence that tobacco control mass media campaigns can be cost-effective should be considered in the context of the evidence from the effectiveness review. The cost-effectiveness evidence base is likely to be biased as only effective campaigns have been evaluated. Furthermore, because the majority of the evidence is from the UK and the USA, the cost-effectiveness findings have limited generalisability.

Chapter 5 What characteristics of mass media campaigns are associated with effectiveness?

Overview

In this chapter we review and analyse evidence regarding the characteristics of mass media campaigns that may be associated with effectiveness. First, we first consider the use of adopting theoretical frameworks encompassing communications and/or behavioural theories in the development, implementation and evaluation of campaigns. We then consider the features of campaign design, including type of media channel used, intervention duration and intensity and intervention content (type of messages, targeting strategies and source) associated with effectiveness. Finally, we consider the evidence on the impact of intervention scale (i.e. whether campaigns are implemented at a local, regional or national level).

This chapter seeks to address the following study objectives:

- 2. examine the components of messages that can be effectively communicated through mass media
- 3. explore how different types and forms of media campaigns can reach and be effective with different target populations (particularly disadvantaged groups)
- 4. assess new or emerging evidence about campaigns that employ different forms of media (including new media)
- 5. examine the relationship between local, regional and national campaigns and evidence of effectiveness where this exists.

The first section of this chapter describes a review of reviews of the effectiveness of campaign characteristics based on the reviews identified for *Chapter 2* (review A). This review included systematic reviews published between January 2000 and January 2016, but it identified limited evidence on the effectiveness of different campaign characteristics, particularly in relation to the UK context and evidence on new media. However, the research team was aware of recent primary studies that have attempted to shed light on these and that are relevant to UK stakeholders, so we subsequently conducted an additional review to identify primary evidence from UK studies (review D). The second section of this chapter therefore describes a review of primary studies (published between January 2011 and September 2016) that provides recent evidence on campaign characteristics conducted in the UK.

Methods: systematic review of reviews

The methods for the review of reviews have been described in *Chapter 2*. From the reviews included in *Chapter 2*, we identified reviews that examined mass media campaign characteristics and synthesised relevant content.

Evidence from the reviews was reviewed and synthesised around the following characteristics of mass media campaigns: theoretical frameworks, intervention duration and intensity, mass media channels used, and intervention content (messages, targeting and source) and intervention scale.

Theoretical frameworks

Given that interventions developed with an explicit theoretical framework are considered more likely to be effective than those lacking any theoretical base,¹³³ we considered that it was important to identify any theories used in the development, implementation and evaluation of campaigns in relation to their effectiveness and whether or not they had used multiple theories to achieve multiple goals. We returned

to all the original included review papers to search the full texts for theory in detail. The earlier data extraction did not always include mentions of theories within introductions and discussions of the papers. We defined a theoretical framework in broad terms as a set of interrelated concepts, definitions and propositions that explain or predict events or situations by specifying relations among variables. From our reading of the reviews, we anticipated that theoretical frameworks would encompass two broad areas – communication theories and behaviour change theories – and that these theories would offer different explanatory insights. For instance, communications theories might help us to understand communication processes in the context of campaigns, such as theories underpinning how best to create and target messages, whereas behavioural change theories might help explain how different people might respond to such messages. By being inclusive, we considered that this would provide a comprehensive analysis of the conceptual thinking underpinning any mass media interventions, and identify the important features that might move people through pathways from increased awareness to eventual behaviour change.

Mass media channels used and interactivity

Mass media campaigns can be run via traditional media channels, such as television, radio, cinema, newspapers, magazines and billboards, or via new digital media including websites, pop-up and banner advertisements, QR codes, viral marketing and social media. New media often feature an element of interactivity (e.g. liking, sharing or commenting on content and downloading campaign apps). This ability to actively engage with a campaign may be associated with the increased effectiveness of a public health campaign. We have assessed the evidence relating to the different media channels used in campaigns, including the types of channels used and the use of single versus multiple channels, and on the use of new interactive media.

Intervention duration and intensity/exposure

Duration refers to the overall length of time that a campaign is in operation. Intensity and exposure refer to the overall 'strength' or 'dose' of a campaign, and can be measured in a number of different ways: the number of different advertisements or media materials produced, the number of times an advertisement is shown, the amount of media spend, the size of the audience reached by the campaign or the percentage of the audience in a given region or area that had a potential opportunity to see the campaign. Duration and intensity/exposure are often closely related, in that the longer a campaign runs, the more likely the audience is to be exposed to it. The two are therefore discussed together in this chapter.

Intervention content: messages, targeting and source

We have examined the evidence on the impact of different types of campaign content. We defined 'message' as referring to the types of messages used in campaigns (e.g. 'positive' vs. 'negative' messages, or messages containing information on the effects of the behaviour or advice on how to change behaviour). 'Targeting' referred to whether the campaign as a whole or specific campaign elements were intentionally targeted at specific population groups. Because the strategic decision regarding targeting was often strongly bound up with choice of messages, these two elements are discussed together. 'Source' refers to the apparent source of the message, and includes the person delivering the message (e.g. the use of actors or testimonials from real people) and the campaign funder (e.g. government, charities or pharmaceutical companies). As the source is likely to be associated with the type of message used and the intended target group, these elements are discussed together.

Intervention scale: local, regional and national campaigns

Even in the context of evidence that mass media campaigns featuring particular characteristics are likely to be effective, decision-makers need to consider how the scale of a campaign may influence its impact. We review the published evidence that considers the differential impact of local, regional and national campaigns.

Results: systematic review of reviews

Use of theory: findings from the review of reviews

Table 12 summarises the number of included reviews of mass media campaigns that examined various aspects of theory, and the various behaviour change theories mentioned in the reviews.

The majority of these reviews did not include a focus on theories or conceptual frameworks or models and, therefore, there was little evidence on the role that theory plays in the effectiveness of the intervention. Eight reviews incorporated theory into the process of their work. Three used logic models to frame their research questions and to identify the outcomes relating to their research.^{47,56,58} These models were not adjusted in the light of the results from the review. One review used the presence of a theoretical framework as one of its inclusion criteria, but did not refer to the theories in the primary studies in the results section.⁶⁵ Leavy *et al.*⁵⁹ used the hierarchy of effects (HOE) framework to specify levels of impact to typify outcomes. Matson-Koffman *et al.*⁶⁰ and Robinson *et al.*⁶⁹ used theoretical framings to provide the rationale for their reviews. Finally, Werb *et al.*⁶³ used theory to explain the findings of their review.

Seven reviews listed the theories they found in their primary studies. Five of these listed behaviour change studies^{27,35,48,57,59} and four mentioned communication theories, notably social marketing.^{27,48,57,59} LaCroix *et al.*⁵¹ mentioned that 45% of the studies in their review were theory based.

In terms of relating theory to effectiveness, in their analysis of the effects of mass media campaigns on drug use, Ferri *et al.*⁶² discovered that two studies based on social learning theory and the social ecological framework produced better results, whereas the study based on the social influence approach favoured the control group.

Mass media channels used and interactivity: findings from the review of reviews

Table 13 summarises the numbers of included reviews that examined media channels or interactivity as potential mediators of effectiveness.

Although most of the reviews included information on the media channels used in the individual included studies, most simply listed them when summarising the characteristics of the included studies, and did not

TABLE 13 Reviews that examined media channels and interactivity

examine media channels or degree of interactivity as mediators of campaign outcomes, or discuss the potential relationship between channels and interactivity and effectiveness. The lack of attention paid to interactivity is unsurprising in the older reviews whose included studies would have predated the development of new interactive media. Findings from the five reviews that reported findings specifically relating to channels are summarised below.

Derzon and Lipsey⁶⁶ conducted a meta-analysis comprising 72 studies of mass media substance use campaigns, with media channels used (radio, television, video or print) as one of the sets of variables in the analysis. Overall, the analysis found that reduced substance use behaviour was associated with exposure to all the different media channels, but that radio was associated with the greatest relative effects ($\Delta = 0.10$) and print with the least ($\Delta = 0.04$). For attitude outcomes, the relative effects were greater for those exposed to video and print rather than other channels. Video was associated with particularly large relative effects on substance use knowledge. In conclusion, the review authors stated that with regard to media channel, messages communicated via video were associated with greater improvements in knowledge, attitudes and behaviour than campaigns that did not use video. It is likely that most of the video-based campaigns would have been implemented in school settings and would have involved discussion and other informational and educational input, in other words in a quite different context from general population mass media campaigns on broadcast media. The age of the Derzon and Lipsey⁶⁶ review (published in 2002) means that some of the studies are likely to be quite old, which again limits the relevance of the findings to the present UK context.

A review of mass media campaigns on HIV/acquired immunodeficiency syndrome (AIDS)-related behaviour among young people in developing countries specifically examined the strength of the evidence for the effects of three types of mass media interventions (radio only, radio with supporting media or radio and television with supporting media) and assessed whether or not these interventions reach the threshold of evidence needed to recommend widespread implementation.⁴⁶ One of the studies included in the review was radio only. Six of the studies evaluated interventions using radio with other supporting media (e.g. written materials, videos, posters, theatre performances and school workshops). The remaining eight interventions involved television and radio with other supporting media.

The review reported that the one radio-only campaign showed mixed results regarding awareness of a helpline but no improvements in social norms, interpersonal communication about HIV/AIDS or various measures of condom use.⁴⁶ Of the six studies using radio with other supporting media, all reported some measure of knowledge gain, although results tended not to be significant, and most studies showed some positive effects on skills, knowledge, interpersonal communication and social norms. Findings relating to various sexual behaviours were mixed, although the weight of the evidence across studies reporting condom use was strongly positive.

Eight studies examined the effect of campaigns using television and radio with other supporting media. Evaluations of this type of intervention generally showed improvements in knowledge and skills related to HIV/AIDS, knowledge about health services, interpersonal communication regarding HIV/AIDS and social norms. Data on different measures of condom use showed positive effects in the majority of studies, although evidence regarding other behaviour change (e.g. reduced age of sexual behaviour, number of partners and abstinence) varied but leaned towards having no effect. The review authors concluded that 'Campaigns that include television require the highest threshold of evidence, yet they also yield the strongest evidence of effects'.⁴⁶ The findings have limited relevance for the UK and OECD countries.

In their review of mass media interventions targeting young people smoking, Richardson *et al.*⁴⁴ reported evidence from a single study on mass media channels, one that examined the effects on youths of antismoking cinema advertisements played during a film. Effects included increased disapproval of smoking in films and, among smokers, a desire to quit. In a wide-ranging review of mixed health behaviours, Mozaffarian *et al.*⁶⁸ noted that mass media and education campaigns using 'multiple modes' (described as including 'print, radio, Internet, television, social networking, other promotional materials') demonstrated effectiveness for increased consumption of specific healthy foods, reduced consumption of less healthful foods and drinks and the promotion of physical activity.

In a review that aimed to synthesise evidence evaluating the effectiveness of mass media interventions on helping people to guit smoking/tobacco use and/or to prevent relapse, Jepson et al.⁴³ presented data in a format that organised the results by channel of mass media. Interventions that drew on two or more forms of the media (such as newspaper, television and billboard advertising) were referred to as 'multichannel' mass media. A particular emphasis was placed on evaluating relevance to the UK setting. Interventions were examined in terms of both the effectiveness of the channel of communication and the effectiveness of message content (see Intervention content: findings from the review of reviews). The review noted that many of the studies used multiple types of media combined with other interventions, which made it difficult to evaluate which particular component was effective or ineffective. It reported some good-guality evidence that the use of technology such as mobile phones could be effective, and offered the potential to deliver culturally specific materials to targeted groups. It also reported evidence that the internet could be an effective way of delivering interventions and may be a particularly appealing channel of communication for young people. Three studies, probably relevant to the UK, found an effect of multichannel mass media on smoking cessation, but there was no evidence about which of the mass media components of the interventions were most effective (or most ineffective), and the review authors cautioned that the results of these studies should be interpreted with caution owing to their poor methodological quality.

One review examined interactivity as a potential moderator of effectiveness. In a meta-analysis of the effects of new-media interventions on sexual health behaviours by Swanton *et al.*,⁵³ the interventions examined included websites, SMS (short message service) messages, social media and online video. Components of interventions were coded as interactive (e.g. personalised e-mails) or static (e.g. watching an online video). Moderation analyses found a variation in the effect of new-media interventions on condom use depending on the interactivity of the new-media channel used:⁵³

Interventions using interactive components yielded significant effects (OR 1.79, 95% CI 1.15 to 2.77; p = 0.01); however, this effect was significantly heterogeneous [Q (6) = 28.03; p < 0.01, $l^2 = 78.59\%$], suggesting that further factors may influence the size of the effect. Interventions using static content did not yield significant effects, and the effect size was homogeneous.

Swanton et al.53

In conclusion, the review found that interventions that used interactive components were shown to be more effective than static components in improving condom use.

Intervention duration and intensity/exposure: findings from the review of reviews

Table 14 summarises the number of included reviews of mass media campaigns that examined intervention duration or intensity/exposure.

Mass media campaign intervention duration and intensity/exposure	Number of reviews
Number of reviews with statistical analysis of effect of intervention duration	2: LaCroix (2014) ⁵¹ and Swanton (2015) ⁵³
Number of reviews with description of an association of effect of intervention duration	4: Bala (2013), ²⁷ Brinn (2010), ³⁵ Mozaffarian (2012) ⁶⁸ and Richardson (2008) ⁴⁴
Number of reviews with no focus on intervention duration or intensity/exposure	30

TABLE 14 Reviews that examined intervention duration or intensity/exposure

Six of the 36 reviews examined or commented on the relationship between intervention duration or intensity/exposure and effectiveness. Information on duration or intensity/exposure in individual studies was extracted in other reviews, but no attempt was made in the review analysis or synthesis to draw conclusions about the relative effectiveness of different levels of duration or intensity/exposure.

Two of the reviews, both examining sexual health campaigns, conducted statistical analysis to examine whether or not intervention effectiveness was moderated by intervention duration.^{51,53} Both found some evidence that effectiveness increases with greater duration and intensity/exposure, although for only some of the outcomes examined. In the meta-analysis of the effects of new-media interventions on sexual health behaviours by Swanton et al.,53 the interventions examined included websites, SMS messages, social media and online video. They were coded into three duration categories (a single session, ≤ 6 months or > 6 months in duration) and the relationship between duration and effectiveness was examined in moderator analysis. Intervention duration was not related to effectiveness in interventions targeting condom use, but was related to effectiveness when the outcome was participation in testing for sexually transmitted infections (STIs): single-session interventions were less effective than longer interventions (up to 6 months in duration, OR 1.64, 95% CI 1.36 to 1.98; p < 0.01; and > 6 months in duration, OR 2.17, 95% CI 1.36 to 3.47; p < 0.01). A meta-analysis of the impact of sexual health mass media interventions on condom use and HIV-related knowledge⁵¹ examined whether or not effectiveness was moderated by various intervention characteristics, including duration and proportion of target population exposed to the campaign. The relationship between campaign characteristics and magnitude of effects was examined using a modified weighted least squares regression analysis. Greater increases in condom use were seen following longer campaigns (k = 51, $\beta = 0.48$, p < 0.001).

Three reviews [one National Institute for Health and Care Excellence (NICE) rapid review⁴⁴ and two Cochrane Database Systematic Reviews^{27,35}] provide some evidence to suggest that intervention duration and intensity/exposure are associated with effectiveness in mass media campaigns targeting tobacco use, but do not examine the relationship statistically. A NICE rapid review of the effectiveness of mass media interventions designed to prevent the uptake of smoking in children and young people examined whether or not the intensity of interventions influenced effectiveness or duration of effect.⁴⁴ Evidence statements in the review stated that:

The duration of a mass media intervention influences its effect. Increased exposure to anti-tobacco messages over time decreases intent to smoke and smoking initiation, meanwhile increasing negative attitudes towards the tobacco industry.

All rights reserved. Subject to Notice of rights. NICE guidance is prepared for the National Health Service in England. All NICE guidance is subject to regular review and may be updated or withdrawn. NICE accepts no responsibility for the use of its content in this product/publication Underpinning support for the evidence statement came from a Cochrane Database Systematic Review (Sowden 1998 as cited by Richardson *et al.*⁴⁴), suggesting that intervention duration was an important influence on behaviours, and from three cross-sectional studies, all conducted in the USA, which found that increased exposure to antismoking advertisements over time resulted in a decrease in young people smoking in the past 30 days (compared with those in markets with no exposure to state-sponsored anti-tobacco laws), intent to smoke, initiation of smoking, enhanced perception of risk and negative attitudes about smoking. The same NICE rapid review⁴⁴ also examined facilitators of and barriers to implementation, and noted that lack of exposure and longevity are barriers to effective mass media interventions, noting that one-off campaigns are not likely to induce behaviour change and that:

Messages must appear frequently enough for audiences to notice them and internalise them. © NICE 2008. Interventions to Prevent the Uptake of Smoking in Children and Young People.⁴⁴ Available from www.nice.org.uk/guidance/ph14/evidence/review-of-effectiveness-pdf-369941869. All rights reserved. Bala *et al.*²⁷ examined the effectiveness of mass media interventions for smoking cessation in adults in a Cochrane Database Systematic Review. From reviewing 11 campaigns, the review concluded that the intensity and duration of campaigns may influence effectiveness, but length of follow-up and concurrent secular trends and events could make it difficult to quantify the effects. The review cited a UK study (McVey 2000 as cited by Bala *et al.*²⁷) that compared the impact of single- and double-weight television campaigns on quit rates and found no significant differences at 6 months, with the single-weight region (Granada) at 6.3% and the double-weight region (Tyne Tees, Yorkshire) at 6.6%, yielding an adjusted OR of 1.02 (p = 0.94). It also discussed studies in other countries that appeared to support the use of longer running or more intense campaigns, but noted that effects may have been confounded by the concurrent presence of other intervention elements such as face-to-face counselling. The authors concluded that 'The duration and intensity of an intervention may affect its impact on smoking behaviour, but evaluations need to last long enough to detect lasting changes, and to allow for confounders and for secular trends'.²⁷

Another Cochrane Database Systematic Review examined the effectiveness of mass media interventions for preventing smoking in young people, with seven studies, all using a controlled design, meeting all of the inclusion criteria.³⁵ The three effective campaigns were all 'of reasonable intensity over extensive periods of time'; in contrast, the campaigns that did not report positive findings, much more heterogeneous in duration and generally shorter. The three effective campaigns comprised (1) 190 television, 350 cable television and 350 radio spots purchased in each of the 4 years during which the campaign was running (Flynn 1995 as cited by Brinn *et al.*³⁵); (2) 167 television and cinema spots in three annual campaigns (Hafstad 1997 as cited by Brinn *et al.*³⁵); and (3) television (local, cable and network), radio, websites, magazines, movie theatres and several other media used over 6.5 years (the National Youth Anti-Drug Media Campaign) (Longshore 2006 as cited by Brinn *et al.*³⁵).

Finally, a wide-ranging mixed-topic review examining the effectiveness of a range of population approaches reported 'strong evidence' that sustained (i.e. longer duration) campaigns are important, particularly for reducing smoking.⁶⁸ The review also noted that some of the campaigns found to be effective in improving diet knowledge and behaviours were implemented for many years, suggesting that 'behavioural changes are sustainable when media and educational campaigns are continued'. However, the effects of mass media campaigns were not distinguished from those of campaigns using multiple approaches including mass media, and the review conducted no statistical analysis of the moderating role of campaign duration. It recommended that media and education campaigns to improve diet, physical activity and smoking should be sustained and should use multiple modes/channels.

Intervention content: findings from the review of reviews

Table 15 summarises the reviews that assess the impact of message type, targeting and source.

Mass media campaign message type, targeting and source	Number of reviews
Number of reviews with message as the primary focus of the review	0
Number of reviews with targeting of specific groups as the primary focus of the review	3: de Kleijn (2015, girls), ³⁸ Gould (2013, indigenous populations) ³⁹ and Guillaumier (2012, disadvantaged groups) ⁴⁰
Number of reviews analysing the effect of the message	12: Abioye (2013), ⁵⁵ Brinn (2010), ³⁵ Brown (2014), ³⁶ Byrne (2005), ⁶⁵ Derzon (2002), ⁶⁶ French (2014), ⁴⁸ Hill (2014), ⁴² Jepson (2006), ⁴³ LaCroix (2014), ⁵¹ Mozaffarian (2012), ⁶⁸ Richardson (2008) ⁴⁴ and Wilson (2012) ⁴⁵
Number of reviews analysing the effect of targeting specific groups	7: Brinn (2010), ³⁵ Brown (2014), ³⁶ Byrne (2005), ⁶⁵ Derzon (2002), ⁶⁶ Jepson (2006), ⁴³ Richardson (2008) ⁴⁴ and Wilson (2012) ⁴⁵
Number of reviews analysing the effect of the 'source' of the message	2: Byrne (2005) ⁶⁵ and Richardson (2008) ⁴⁴
Number of reviews with no specific analysis of message or targeting of specific groups (had intended to look at targeting or messaging but not enough studies)	20
Types of message	Social norms, guided by theoretical concepts, personal testimony, highly emotive, graphic, negative health consequences, fear campaigns and strategies for refusal
Nature of targeting	Low education, low SES, age, youths, girls, cultural indigenous and ethnic groups
SES, socioeconomic status.	

TABLE 15 Reviews that examined message, targeting and source

Although the majority of reviews provide some detail on the content of mass media interventions, often including some detail about the message and target population for individual studies and campaigns, only 12 provided some degree of analysis or synthesis of the influence of message type on behavioural or other outcomes. A further 10 provided analysis or synthesis of the effectiveness of the targeting of campaigns. The main focus of three reviews was the effectiveness of targeting campaigns towards specific groups (girls, indigenous populations and disadvantaged groups), whereas none focused solely on the characteristics of effective messages. There is a clear overlap between reviews that provide information on effect of message type and effect of targeting, which is reflected in the summary below.

Message types

A number of reviews provide evidence that intervention content influences effectiveness. An evidence statement in the NICE review on preventing uptake of smoking by children⁴⁴ states:

The way in which an intervention is delivered does influence effectiveness. However effectiveness is dependent on a number of factors including message content, mode of delivery, target audience, message framing and message elements.

© NICE 2008. Interventions to Prevent the Uptake of Smoking in Children and Young People.⁴⁴ Available from www.nice.org.uk/guidance/ph14/evidence/review-of-effectiveness-pdf-369941869. NICE accepts no responsibility for the use of its content in this product/publication

There were some consistent themes among those reviews that compared message types.

Several reviews found that campaign messages that intended to denormalise behaviour, including social norm campaigns, may be more effective across a range of behaviours, including physical activity in adults, smoking in adults and substance use in the young, than some other message types.^{44,55,65,66} In their review of health campaigns to increase physical activity, Aboiye *et al.*⁵⁵ noted that campaigns based on 'social norm' messages were more likely to lead to a reduction in sedentary behaviour (RR 1.33, 95% CI 1.01 to 1.43) than those using celebrities or based on a 'risk message' (RR 1.05, 95% CI 0.92 to 1.21). Richardson *et al.*⁴⁴ provided evidence from one qualitative study that social norms messages were more effective than fear messages at encouraging more committed young smokers to consider their smoking behaviours and reinforcing awareness of the dangers of smoking in less committed smokers. The review by Byrne *et al.*⁶⁵ examining various substance use behaviours in young people found that a denormalisation message was used in 13 campaigns, and most of these (89%) were associated with positive outcomes in the three domains of attitudes, knowledge and behaviour. A meta-analysis on a similar theme by Derzon and Lipsey⁶⁶ did not report any particularly large effects for their category 'perceived normative use' but did note that positive attitudes to non-use, which would arise from denormalisation messaging, were associated with positive outcomes regarding behaviour, attitudes and knowledge.

Several reviews highlighted that messages concerning negative health consequences, mostly anti-tobacco messages, can be effective; however, for the most part negative messages were not directly compared with positive messages.^{43-45,65,68} In a broad-ranging review of mixed health behaviours, Mozaffarian *et al.*⁶⁸ noted that factors that increase effectiveness for tobacco campaigns include use of strong negative messages about health. A review by Byrne *et al.*⁶⁵ of campaigns addressing various substance use behaviours in young people found that 14 campaigns, representing 56% of the total number of campaigns evaluated, employed health effects messages using information about the negative health effects of substance use in order to effect change in attitudes, knowledge, behaviour or all of these, and 79% were associated with positive outcomes.

In a review of mass media campaigns promoting antismoking messages, Wilson et al.45 found that message content and tone contributed to heterogeneity in effects, and suggested that, although it is not clear which types work best, adult audiences are most likely to respond to graphic depictions of health consequences of smoking; this evidence is primarily based on the effectiveness of hard-hitting graphic campaigns from Australia. In the NICE rapid review of campaigns to prevent uptake of smoking by children, Richardson et al.⁴⁴ reported evidence from one RCT suggesting that tobacco-related disease messages were effective for increasing anti-tobacco attitudes in the young and another RCT suggesting that message content could change perceptions of health risk severity and intentions not to smoke; both studies were from the USA and the review concludes that it is not clear if these findings are directly applicable to the UK. In a review of mass media campaigns to encourage smokers to quit, Jepson et al.⁴³ found little direct comparison between message types, but this review resulted in the following evidence statements: (1) there is level 2 evidence, probably relevant to the UK population, which suggests that advertisements depicting suffering as a result of tobacco use may be instrumental in promoting cessation or reinforcing the decision to guit and (2) there is level 3 evidence that shows that graphic mass media messages about negative consequences of smoking among adults also have a positive effect on quit attempts among young people. Finally, there is level 2 evidence providing insufficient evidence that longer positive messages are less effective than short negative messages. However, this review concluded that although a few studies have evaluated different message styles (e.g. fear arousing), there was not enough evidence to determine which messages were more effective than others. They point out that smokers and reasons for smoking are complex and smokers are not simply compelled to guit because of fear/negative messages.⁴³ One aspect of note here is the addictive impact of nicotine on attempts to guit smoking, although this is rarely mentioned in the context of messaging.

Reviews highlight some messages that appear to be less effective or for which the evidence is less convincing. Both Byrne *et al.*⁶⁵ and Derzon *et al.*⁶⁶ found that those campaigns emphasising resistance or refusal skills for substance use behaviours in the young were less effective. Byrne *et al.*⁶⁵ noted that one campaign promoting such skills was associated with an increase in the intention to take up smoking among young people, although this campaign was funded by a tobacco company and did not contain messages about the harmful effects of smoking.⁶⁵ In a similar vein, the review by Derzon *et al.*⁶⁶ showed gain in terms of knowledge with this message but not in terms of behaviour and attitudes.

The effectiveness of tobacco industry deception or truth campaigns for the young was discussed in several reviews with some mixed evidence between studies.^{44,45} Richardson *et al.*⁴⁴ reported evidence from several US cross-sectional studies that 'truth' messages were effective in decreasing and preventing smoking in youth, although they point out that the American Legacy Foundation's Truth campaign is a specific US campaign and results may not be directly relevant to other contexts including the UK.⁴⁴ They also report a RCT that found that anti-industry advertisements did not decrease young people's intentions to smoke, and a qualitative study that found that advertisements focused on the marketing and manufacturing practices of the tobacco industry, presenting the industry as greedy and deceitful, were aesthetically appealing but ineffective for preventing the uptake of smoking. Wilson *et al.*⁴⁵ in their review of interventions for smoking, reported that, among US youths, large-scale campaigns focused on tobacco industry manipulation and deception were shown to be effective at reducing initiation.

Target audience

A dominating theme from a number of reviews is that message effectiveness depends on the target audience and appropriateness of the message to the target audience.^{35,43–45,48,51,65,68} The review by Mozaffarian et al., 68 which examined population approaches across multiple behaviours (diet, physical activity and smoking), noted that 'broad community-based media and educational programmes that target multiple cardiovascular risk factors and behaviours simultaneously have been less successful, which suggests the importance of focused messages for the target audience'. Byrne et al.,⁶⁵ having looked at campaigns across a mixture of behaviours, indicate that mass media messages need to take into account the age, sex, culture, level of engagement in the target activity and personal characteristics, such as sensation-seeking, of the intended audience. Although these reviews considered multiple behaviours, even reviews that have considered only one lifestyle behaviour have suggested that no one message seems to be more or less effective across the board, and reason that we should not expect one style of message to resonate with all.^{43,44} The reviews covering smoking alone suggest that smokers are complex and the reasons for smoking are complex, and the outcomes of any message type depends on the context and the values that the audience associates with smoking.^{43,44} Broadly, the message needs to have relevance for the target audience and to have the right content, format, tone and level of complexity for the audience; any imagery needs to complement the campaign message.48

Several reviews examine if and how campaigns should be targeted to reach specific subgroups, for example youths, disadvantaged or less-educated populations, indigenous populations and other ethnic groups. There is evidence of effective campaigns targeting these groups.^{35,39,40,43} In the review by Brinn *et al.*³⁵ of mass media interventions to prevent smoking in young people, two of the three studies successfully reducing smoking behaviour targeted specific populations: one targeted girls and one targeted higher risk groups, defined by parental education attainment and income levels. Guillaumier *et al.*⁴⁰ reported that antismoking campaigns developed for, marketed to and evaluated with disadvantaged groups only were successful in achieving recall and response. Jepson *et al.*⁴³ found a lack of evidence for effectiveness on smoking outcomes of campaigns targeted at pregnant women who smoke and mothers of young children. However, they report that culturally appropriate advertising materials, which target particular ethnicities or

communities, have been found to be effective by a number of studies, including materials targeting rural Nebraskan oral tobacco users with cowboy images, using gospel, jazz music and images appropriate to African American communities, or targeting the community with own-language materials, as in the case of Vietnamese Americans. However, they note that ethnicity is also crosscut by different income and educational levels and there is a need to be sensitive to the pitfalls of developing campaigns that may simply reproduce social or cultural stereotypes. It is important that the message does not stereotype or patronise; targeted campaigns need to be culturally appropriate and relevant.³⁹

Few reviews provide examples of how to target the message for specific populations. A review by Brown *et al.*³⁷ considered the equity impact of interventions to reduce smoking in adults; it found mixed evidence in terms of the equity of campaigns overall, but provided evidence from studies showing that highly emotive and personal testimony advertisements were more effective with low-socioeconomic-status groups and that emotive or graphic advertisements were more effective with low-socioeconomic-status smokers. Hill *et al.*⁴² found weak evidence that antismoking television advertisements using personal testimony are more likely to have neutral equity impact for socioeconomic inequalities than traditional information-based advertisements, which tended to have greater impact among high-socioeconomic-status smokers. Gould *et al.*³⁹ point out that, for New Zealand Māori, mainstream graphic advertisements showing body parts are inappropriate.

Nevertheless, generic campaigns aimed at the general population can also be effective in reaching specific subgroups such as the young, disadvantaged smokers or indigenous populations.^{39,40,44} Adult-focused or general population campaigns are successful in reducing smoking in young people.⁴⁴ Looking across different types of substance misuse, Derzon and Lipsey⁶⁶ suggest that bigger effects are obtained by targeting parents and other youth-influential adults rather than the youths themselves. Although some studies suggested that targeted campaigns are preferred by indigenous populations, even in these subgroups, generic campaigns were as effective in terms of recall as more targeted campaigns, although it was less clear whether or not recall translated into behaviour change.³⁹ Guillaumier *et al.*⁴⁰ noted that when general population and targeted campaigns, both airing nationally, were compared in disadvantaged-only samples, disadvantaged smokers were more likely to recall and respond to the generic campaigns than to the targeted campaigns, suggesting that general population campaigns have the potential to be effective with disadvantaged population subgroups.

Source

There is some indication that the source of the mass media message can also be important; however, this issue is addressed in only a small number of reviews. Furthermore, the source of the message is often reflected in the message type and, therefore, its effect cannot be easily disentangled. Similarity between the source and the audience may increase persuasive impact, for example teenage actors for campaigns aiming at young people.⁶⁵ Several reviews conclude that campaigns produced by the tobacco industry are not effective and may even be harmful, perhaps because the messages used hold less negative emotional appeal to the young than campaigns organised by tobacco control programmes.^{44,45} In an evidence statement, Richardson *et al.*⁴⁴ conclude that, when comparing intervention source, prevention campaigns produced by the tobacco industry are less effective than anti-tobacco campaigns produced by tobacco control bodies. Youths perceive industry campaigns to be less effective, less interesting and less engaging.

Intervention scale: findings from the review of reviews

None of the reviews examined scale of campaign as a potential mediator of effectiveness. Although the reviews noted whether their included studies were implemented at local, regional or national levels, most simply listed the information and none of them provided any evidence or commentary regarding the relative effectiveness of campaigns implemented at these different levels or discussed factors that might be associated with effectiveness when campaigns are implemented at the different levels.

Methods: review of recent UK primary studies

In the UK, some primary studies have recently sought to assess the contribution of different media campaign characteristics to campaign effectiveness. In order to address the gaps in the review of reviews and to examine evidence with relevance to the current UK context, we conducted an additional review of UK primary studies published between January 2011 and September 2016 (review D). The focus of this review was on evidence concerning the characteristics of UK mass media campaigns associated with effectiveness, rather than on the effectiveness of those campaigns per se.

Identification of studies

Studies were eligible if the paper was published in or after 2011 and the study was conducted in the UK. Multicountry studies were eligible if findings for the UK were reported separately. The campaigns had to address one of our six health topics: alcohol use, illicit substance use, diet, physical activity, sexual and reproductive health and smoking cessation and prevention. Apart from targeted health topics, the study eligibility criteria for primary research studies evaluating the effectiveness of mass media interventions were the same as those used in the related review of mass media campaigns to reduce alcohol consumption.¹⁷ *Box 3* describes the mass media campaign intervention study eligibility criteria. Studies could report data or outcomes of any format for the following outcomes: behavioural or social cognitive outcomes, media outcomes (e.g. recall, understanding and onward transmission of the campaign) and distal (e.g. societal or policy changes) or process (e.g. cost-effectiveness) outcomes. Studies of multicomponent interventions were eligible if they assessed the specific effects of a mass media component, and published conference abstracts were eligible provided there was a description of the campaign and outcome data were reported.

BOX 3 Mass media intervention eligibility criteria (review D)

Eligible studies

 Mass media campaigns broadcast using television, radio, cinema, online broadcasting, newspapers and magazines, leaflets/booklets, direct mail, outdoor advertising, text messaging, e-mail and digital media, including websites and banner advertisements.

Ineligible studies

- Interventions involving person-to-person contact, requiring active engagement before receipt of the message (e.g. alcohol screening questions) rather than passive message exposure, or online treatment or self-help programmes.
- Studies in which a baseline measure is used to tailor a subsequent mass media message.
- Studies testing campaign messages rather than assessing implemented campaigns intended to reach large numbers of people. Exclude studies of messages taken from an implemented campaign but delivered and evaluated outside that campaign (e.g. in laboratory conditions).
- Studies of multicomponent interventions if they do not assess the specific effects of a mass media component.
- Studies assessing the impact of advertisement bans.
- Studies of social norms campaigns unless it is evident from the information available that a mass media channel was used. If an intervention is described only as a social norms or social marketing campaign and there is no information indicating the use of mass media channels then it will be ineligible for inclusion.
- Studies of obligatory health warnings (e.g. on-pack health warnings and point-of-sale health warnings) and studies evaluating policies rather than campaigns.

The search strategy was a revision of that used for the project's review of mass media campaigns to reduce alcohol consumption, combining terms for mass media and health communication campaigns and for the target health topics with a UK studies search filter (see *Appendix 6* for an example strategy). Sixteen academic databases were searched on 7–9 September 2016 and the results were uploaded to an EPPI-Reviewer 4 database and deduplicated (*Figure 4*):²⁶

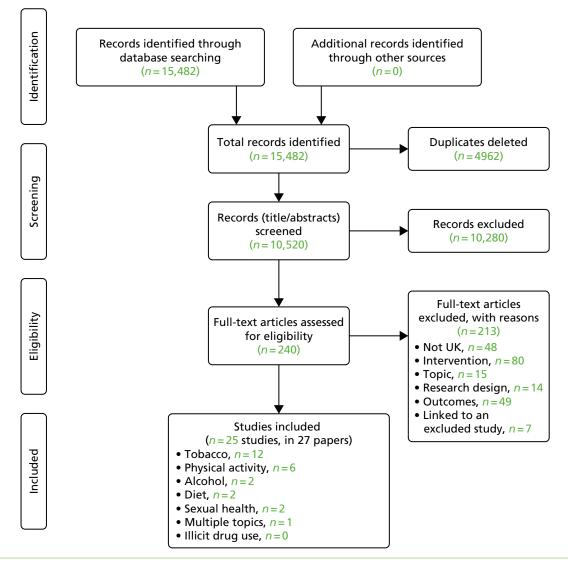

FIGURE 4 The PRISMA flow diagram of the identification and selection of primary studies (review D).

Records (n = 10,520) were screened for initial topic relevance, date and country by two reviewers (KH and KA). One per cent (n = 105) of randomly selected records were double-coded to pilot the screening process and check for inter-rater reliability. Once agreement was > 90% on included and excluded categories, then a proportion of the rest was allocated to each reviewer for single coding. The resulting 240 were retrieved as full texts and all double-coded by the reviewers (KH and KA) for inclusion; any final decision disagreements were resolved by a third reviewer (LB or MS). Twenty-seven papers covering 25 recent evaluations of UK mass media campaigns were included for analysis (see *Appendix 7*).^{119,120,134–158} A list of UK primary studies excluded by full-text assessment is provided in *Appendix 8*.

The data extraction form was a revision of that used for the project's review of reviews and designed to capture the study methods and outcome data as well as details of the mass media campaigns (the intervention) towards answering the project's objectives. Studies were double data extracted independently by three reviewers [KA, KH and Joanne Morrison (JM)], who held telephone meetings in pairs to agree and finalise the data for each study. A pilot data extraction exercise, using two studies independently coded by all three reviewers, familiarised them with the process to ensure consistent interpretation of the headings. No study authors were contacted in order to obtain or confirm data.

In a departure from the review project's protocol, two additional risk-of-bias appraisal tools were added after study selection to correspond to the included studies' design. The proposed EPHPP Quality Assessment Tool for Quantitative Studies was used to assess experimental studies,⁷⁸ with the additional US National Institutes of Health's assessment tool for observational cohort and cross-sectional studies¹⁵⁹ and the Critical Appraisal Skills Programme (CASP) tool for qualitative studies.¹⁶⁰ Studies were appraised for quality and relevance (at a study level) independently in duplicate by three reviewers (KA, KH and JM), who held telephone meetings in pairs to agree and finalise the risk-of-bias assessment for each study. The pilot exercise described above also included an independent appraisal of quality and relevance for the same two studies by all three reviewers.

This review of recent UK primary studies was designed to capture data or outcomes of any format for the following outcomes: (1) behavioural, social cognitive or media outcomes and (2) distal (e.g. societal or policy changes) or process (e.g. cost-effectiveness) outcomes. Thus, from its inclusive nature, we did not expect to be able to carry out a meta-analysis of the data.

Narrative synthesis

Evidence from the UK primary studies was reviewed and synthesised around the following characteristics of mass media campaigns: theoretical frameworks, intervention duration and intensity, mass media channels used and intervention content (messages, targeting and source) and intervention scale. How these characteristics were defined and analysed is described in *Methods: systematic review of reviews*.

Results: review of recent UK primary studies

Use of theory: findings from the review of UK primary studies

Table 16 summarises the numbers of included UK primary studies that examined various aspects of theory, and the various behaviour change theories mentioned in the studies.

Out of 23 primary studies, 17 did not include grand theories, conceptual frameworks or models to inform their mass media interventions. Of the six studies that did incorporate theory, three grand theories were identified: 'social contagion theory' to amplify a campaign by normalising a behaviour and turning it into a movement;^{120,136} 'prime theory' (plans, responses, impulses/inhibitory forces, motives and evaluations) to alter people's desires to succeed in changing maintaining patterns of behaviour through increasing motivational inputs;^{120,136,152,153} and 'theory of planned behaviour' to alter behaviour through influencing people's intentions to perform such behaviours.^{139,140} One further study mentioned using theoretical ideas rather than identifying a specific grand theory, by drawing on ideas from social marketing and behaviour

Use of theory	Number of UK primary studies
Number of studies with theory as integral to study or programme design	6: Brown (2014), ¹²⁰ Brown (2016), ¹³⁶ Eves (2012), ¹³⁹ Eves (2012), ¹⁴⁰ Richardson (2014) ¹⁵² and Richardson (2014) ¹⁵³

Number of studies with no focus on grand theory	19

TABLE 16 The UK primary studies that included theory

change, but in this study it was unclear how these ideas were used.¹³⁸ Across the studies, there was no mention of using other theoretical frameworks or logic models to inform their research questions or to identify the outcomes relating to their research.

In terms of how theory was used in the basis of the programme design, in the study by Brown *et al.*,¹²⁰ social contagion theory was used to piggyback onto an annual 'no smoking day' that aimed to help smokers stop by providing a nationally supportive environment and drawing attention to available treatments; they also developed a national cessation campaign (Stoptober) to generate a burst of activity around key time points when quit rates had reduced. In a later study, Brown *et al.*¹²⁰ used 'prime theory' to refine film content on the basis of focus group testing with a diverse group of smokers.¹³⁶ Using 'theory of planned behaviour' to alter behaviour through influencing people's intentions, Eves *et al.*¹³⁹ tested the success of two different messages in encouraging more physical activity in members of the public.

Mass media channels used and interactivity: findings from the review of UK primary studies

Table 17 summarises the different mass media channels examined in the review of UK primary studies.

As can be seen, only one of the studies compared different media channels within the same study.¹⁴³ This was a tobacco control social media campaign that aimed to raise awareness about the health risks of waterpipe tobacco smoking. The number of Facebook (Facebook, Inc., Menlo Park, CA, USA; www.facebook.com) subscribers, Twitter (Twitter, Inc., San Francisco, CA, USA; www.twitter.com) followers and YouTube (YouTube, LLC, San Bruno, CA, USA; www.youtube.com) views all increased over time (measures taken at 3, 6 and 9 months). In a descriptive comparison of interactions with the social media channels, the authors concluded that Twitter provided the most organisation-based contact (e.g. 8% of tweets were retweeted, and nearly two-thirds were on health effects of waterpipe tobacco and other Twitter users interacted with @shishaware 70 times), whereas Facebook was the most interactive channel (e.g. 69% of status updates had more than one 'like', 23% had more than one comment from users). The YouTube channel had also been 'favourited', had 'likes' and 'dislikes' and had a rate of 112.2 comments per 10,000 views.

Media channels used and media channel interactivity	Number of UK primary studies
Number of UK studies that compared effectiveness of different media channels within the same study	1: Jawad (2015) ¹⁴³
Number of studies with no focus on media channels and interactivity	24

TABLE 17 The UK primary studies that examined media channels and interactivity

The remainder of the UK primary studies reported the channel(s) used in the campaigns, but did not provide evidence comparing or commenting on the effectiveness of different channels.

Intervention duration and intensity/exposure: findings from the review of UK primary studies

Table 18 summarises the number of UK primary studies that examined intervention duration or intensity/exposure.

Eleven of the 25 recent UK primary studies commented on or examined the relationship between mass media intervention duration or intensity/exposure and effectiveness.

A series of six related statistical studies evaluated televised tobacco control campaigns broadcast in England (2002–10) by examining existing data sources and indicators of smoking behaviour against detailed population-level campaign exposure data.^{144,148,152–155} Exposure data used the standard advertising industry measures of a campaign's reach [gross ratings points (GRPs)] and its reach and frequency [television ratings (TVRs)]. The standard advertising industry measures of GRPs are equivalent to the summed ratings of individual advertisements across multiple campaigns, giving a per capita measure of advertising exposure. TVRs are defined as the percentage of a particular audience that has seen a commercial break.

An analysis using 4 years of longitudinal panel data from the International Tobacco Control UK Survey found that increased exposure (as measured by GRPs) was associated with higher recall at 6 months, although participants were recalling any advertising or information that talked about the dangers of smoking or encouraged quitting on television – not specifically tobacco control campaigns.¹⁵³ The effect was significant only for recent exposure (OR 1.51, 95% CI 1.14 to 2.01); exposure in the 4–6 months before the survey had no impact on recall.

An analysis of monthly Opinions and Lifestyle Survey data found a small association between increased exposure (by 400 GRPs) to television adverts, equivalent to all adults in the population seeing four tobacco control television adverts per month, and a 3% lower odds of smoking (OR 0.97, 95% CI 0.95 to 0.999; p = 0.044) a couple of months later, and a 1.80% (95% CI 0.47 to 3.11; p < 0.01) decline in average daily cigarette consumption 1 month later.¹⁵⁵ Further analyses of exposure by emotive characteristics of the messages in the advertisements are reported in *Intervention content: findings from the UK primary studies*.¹⁵⁴

Mass media campaign intervention duration and intensity/exposure	Number of UK primary studies
Number of studies that compared effects of level of intervention duration or intensity/exposure on smoking outcomes. Exposure data used the standard advertising industry measures of a campaign's reach (gross rating points) and its reach and frequency (television ratings)	6: Langley (2012), ¹⁴⁴ Richardson (2014), ¹⁵² Richardson (2014), ¹⁵³ Sims (2014), ¹⁵⁵ Lewis (2015) ¹⁴⁸ and Sims (2016) ¹⁵⁴
Number of studies that compared effects of level of intensity/exposure, alongside message types/content, on stair use for increasing physical activity	3: Eves (2012), ¹⁴⁰ Lewis (2011) ¹⁴⁵ and Lewis (2012) ¹⁴⁷
Number of studies that compared effects of sexual health campaign. Exposure calculated by comparing three levels of campaign recall and recognition	1: Flowers (2013) ¹⁴¹
Number of studies that compared effects of level of intervention duration to improve diets	1: Capacci (2011) ¹³⁷
Number of studies with no focus on intervention duration or intensity/exposure	14

TABLE 18 The UK primary studies that examined intervention duration or intensity/exposure

In an analysis of time series data of quitline calls and NRT over-the-counter sales and prescribing data against exposure to anti-tobacco mass media advertising and smoking cessation medication advertising,¹⁴⁴ there was some evidence that effects on those information- and treatment-seeking behaviours tended to peak in periods of greater campaign exposure (TVRs were higher in January and were highest in January 2005 and 2010). This suggests that exposure is associated with effectiveness. More specifically, a 1% increase in tobacco control TVRs led to a 0.129% increase in quitline calls in the same month (or a 0.085% increase in the seasonally adjusted model, p = 0.007). For NRT, in most years there was a clear peak in prescribing in the first 3 months of the year and a much smaller peak in October and in January to March each year there were generally peaks in over-the-counter NRT sales. A 1% increase in pharmaceutical company TVRs led to a 0.05% increase in sales in the same month; however, this finding was not statistically significant in the adjusted model. A further study evaluated the impact of different types of message in national campaigns on calls to the English NHS Stop Smoking telephone helpline.¹⁵² Exposure to all types of campaign (as measured by GRPs) was associated with increased calls to the helpline (see *Intervention content: findings from the UK primary studies* for findings for message types).

Looking at the impact of the campaign on smoke-free homes, Lewis *et al.*¹⁴⁸ found that level of exposure to all tobacco control campaigns (measured by GRPs) was not associated with increased likelihood that a home would be smoke-free, but level of exposure to second-hand smoking campaigns was associated with an increased likelihood that a home would be smoke-free, with increased exposure being associated with increased odds (by 7% for each additional 100 GRPs) at a 1-month lag after the campaigns (OR 1.07, 95% CI 1.01 to 1.13; p = 0.033). There was no significant association during the same month of the campaign (OR 0.99, 95% CI 0.93 to 1.05; p = 0.740) or 2 months after (OR 0.98, 95% CI 0.92 to 1.04; p = 0.490), suggesting that the impact of the second-hand smoking campaign did not happen immediately and that it also fades quickly.

A series of naturalistic studies evaluating local point-of-choice prompts in public places (e.g. multistorey workplaces and railway stations) to encourage stair use for increasing physical activity varied the numbers of posters and signage shown throughout the experimental period.^{140,145,147} This variation in intensity of exposure was tested alongside variations in message types, and the findings are reported in *Intervention content: findings from the UK primary studies*.

One study evaluated a regional 10-month sexual health poster, leaflet and online campaign (2009–10) in the west of Scotland aimed at men who have sex with men.¹⁴¹ Survey results were analysed by the extent of respondents' exposure to the campaign (their recall and recognition of the campaign). At the end of the campaign, greater exposure was associated with positive changes for some but not all outcomes. For example, those with no exposure were significantly less likely to report always using appropriate lubricant than those with low exposure (adjusted OR 0.42, 95% CI 0.23 to 0.77; p = 0.005); however, those with high exposure to the campaign did not differ significantly from those with low exposure.

Finally, one study evaluating a 2003–6 national mass media campaign to improve diets reported behavioural outcomes annually throughout the radio, television and online campaign.¹³⁷ The campaign to encourage consumption of five portions of fruit and vegetables per day used 'mini campaign relaunches' every 6 months; although the overall aim was the same, each relaunch targeted a different subpopulation (by income, age or sex) and used slightly different methods and channels. Significant campaign effects for increased fruit and vegetable intake did not happen until the third year of the campaign and the effect was stronger for those in lower income groups. The fact that significant impacts did not emerge until the third year of the campaign may suggest that campaigns need to last a certain length of time before effects are felt, although the authors suggest that the delay in impact may have been partly attributable to the nature of the activities in different phases of the campaign, with earlier phases involving a lower investment in targeted advertising.

Intervention content: findings from the UK primary studies

Table 19 summarises the UK primary studies that assess the impact of message content.

The UK evidence on different types of message and campaign content is based on nine studies on two types of behaviour: physical activity (four studies) and smoking (five studies).

The UK has been exposed to very diverse tobacco control campaigns and is therefore a good setting in which to investigate the effect of different types of messages. Several studies on tobacco campaigns investigate the differential impact of 'positive' (eliciting happiness, satisfaction or hope) and 'negative' (eliciting fear, sadness, guilt, anger or disgust) messages^{152–154} and find that both are effective. Unlike negative messages, positive messages have not been found to have an effect on recall,¹⁵³ but both positive and negative messages have been shown to influence information-seeking¹⁵² and smoking behaviour,¹⁵⁴ with positive campaigns having a bigger effect. This indicates that recall does not necessarily translate into changes in behaviour, which should be taken into account in studies assessing the 'effectiveness' of campaigns by measuring recall.

There is evidence from one study that the source of the campaign is important,¹⁴⁴ with government- and charity-funded campaigns being more effective at triggering quitting behaviour than pharmaceutical company-funded campaigns. None of the primary studies compared the effects of targeting on specific groups; however, one primary study reports that targeted campaigns about the risks of second-hand smoke exposure increased the odds of a home being smoke-free more than tobacco control campaigns overall.¹⁴⁸

The physical activity studies are based on poster campaigns to increase stair use. They suggest that multicomponent messages (e.g. providing information on calories burned as well as posters directing people to the stairs) delivered at the point of choice (or 'volitional' messages) are more effective than those that have a single component and/or are 'motivational'.^{140,145,146} One of the physical activity studies suggests that simple messaging may be more effective in busy settings.¹⁴⁷

Intervention scale: findings from the review of UK primary studies

None of the UK primary studies examined whether or not scale (i.e. whether a campaign was implemented at a local, regional or national level) was a potential mediator of effectiveness.

Mass media campaign message type, content, targeting and source	Number of UK primary studies

TABLE 19 The UK primary studies that compare effects of different message types, content, target or source

Summary

We reviewed evidence regarding characteristics of mass media campaigns that may be associated with effectiveness. Evidence was drawn from the review of reviews (reported in the previous sections and see *Chapter 2*) and from an additional review of recent UK primary studies (published between 2011 and 2016).

Overall, there was limited evidence from the reviews on the contribution of media campaign characteristics to effectiveness, with only a small number of reviews containing statistical analyses to assess the impact of different characteristics. There was little evidence regarding the role that theory may play in campaign effectiveness, with most reviews simply listing which theories, if any, had been referred to in intervention studies. There was limited evidence regarding media channel as a potential moderator of effectiveness in three reviews, with findings varying depending on the types and topics of campaigns, and mostly having limited relevance to the contemporary UK context. Longer intervention duration or greater intensity/ exposure were found to be related to effectiveness in several reviews, with most of the evidence relating to tobacco and to a lesser extent to sexual health campaigns; however, there was little clear guidance or consensus on how long or intense campaigns should be to produce effects. Lack of formal statistical analysis in the reviews meant that clear conclusions about the type of messaging content that is most effective could not be drawn. There was evidence from the reviews that social norms campaigns and negative messaging (i.e. hard-hitting messages on health consequences) could change behaviour but little evidence regarding whether or not these were more effective than other approaches. The reviews indicated that targeting can be effective, suggesting that messages need to be appropriate to the target audience taking into account a range of characteristics including age, sex, culture and level of engagement in the activity. There was evidence to suggest that targeting specific subgroups such as the young could be effective, but with caution to avoid patronising or stereotyping. There was no evidence from the reviews on the scale of campaign (i.e. whether it was implemented at a national, regional or local level) acting as a moderator of effectiveness. Regarding source, there was evidence that tobacco industry-sponsored campaigns were not effective.

There was limited evidence from the review of UK primary studies (which were mostly concerned with tobacco, plus a small number of physical activity interventions) regarding the use of theory as a potential moderator of campaign effectiveness. Only one study compared different media channels within the same study (a comparison of audience engagement through different social media channels). Evidence from the primary studies regarding intervention duration or intensity/exposure as moderators of effectiveness was consistent with that from the reviews, generally finding that more sustained and greater intensity campaigns were more effective. A benefit of reviewing the UK primary studies' evidence was that a greater mix of message types have been evaluated, and this evidence suggests that positive messages may also be important, with both positive and negative messages affecting smoking behaviour. Regarding messages for physical activity, there was mixed evidence regarding effective messages for poster campaigns promoting stair use. There was limited evidence that government and charity campaigns may be more effective than those from pharmaceutical companies. As with the reviews, there was no evidence regarding scale as a moderator of effectiveness.

Chapter 6 Stakeholder engagement

S takeholders have been engaged throughout the study but particularly in the development and initiation of the research and the interpretation of findings. This includes public engagement. In this chapter, we describe stakeholder and public engagement in:

- developing the study
- refining research plans
- interpreting findings.

Development of the study

The research questions for the study were shaped by the commissioning brief from NIHR, but we involved stakeholders and particularly the public in preparing the application. The principal investigator (PI) of the study is the public engagement lead for the UK Centre for Tobacco and Alcohol Studies (UKCTAS). UKCTAS convenes public engagement groups on smoking and alcohol use: two of the main public health issues covered by our research. The PI set up a smokers' panel (of smokers and recent ex-smokers) in Bath, when she was based at the University of Bath prior to this study, and the panel started meeting in 2008. The panel was reconstituted at the University of Nottingham, another UKCTAS university also involved in this study, from 2011, when the PI moved to Stirling. The Nottingham panel helped shape the study scope, particularly commenting on key aspects of the proposal including the plain English summary. After the study was initially considered for funding by NIHR, the PI had established an alcohol public engagement panel at the University of Stirling and the research proposal was discussed with the university at the time when the proposal was resubmitted before funding was secured.

Two initial lay members for the study were identified from the smokers' panel when it was held in Bath and another previous study from the team on smoking in pregnancy. However, 2 years passed between the initial development of the outline for the study and funding being secured and contact was lost with the Bath-based panel member while the smoking in pregnancy lay adviser moved on to support another study conducted by the PI's research team. When the study began, we were pleased to secure the involvement of Mr George Vekic, who served as public and patient involvement (PPI) representative on the study advisory group. Mr Vekic is a member of the UKCTAS alcohol discussion group and also works as a digital media officer, so had an interest in the study topic.

Stakeholders from a range of organisations were also involved in developing the study. The research team consulted colleagues at Health Scotland, the Scottish Government and the Department of Health and Social Care while developing the study proposal. We also engaged academic and practice colleagues who subsequently agreed to join our advisory group. This included representatives from two Collaborations for Leadership in Applied Health Research and Care (CLAHRCs): one in north London (links facilitated by research team members at University College London) and the other in the East Midlands (links facilitated by research team members at the University of Nottingham).

Refining research plans

As the study developed, we continued to engage with professionals and the public. In particular, we sought input on the development of the logic model for the study. The initial model was discussed with the project advisory group, the UKCTAS smokers' panel, the UKCTAS alcohol public engagement group (including our PPI representative Mr Vekic) and representatives of two CLAHRCs: East Midlands and North Thames. Their response to the model helped refine its content and make more explicit the assumptions underpinning the relationship between the resources and activities in the model and the range of possible outcomes that we expected might arise from public health mass media campaigns.

[©] Queen's Printer and Controller of HMSO 2019. This work was produced by Stead *et al.* under the terms of a commissioning contract issued by the Secretary of State for Health and Social Care. This issue may be freely reproduced for the purposes of private research and study and extracts (or indeed, the full report) may be included in professional journals provided that suitable acknowledgement is made and the reproduction is not associated with any form of advertising. Applications for commercial reproduction should be addressed to: NIHR Journals Library, National Institute for Health Research, Evaluation, Trials and Studies Coordinating Centre, Alpha House, University of Southampton Science Park, Southampton SO16 7NS, UK.

Initial findings from the review of reviews element of the study were circulated to members of both the UKCTAS public engagement panels and members reflected on their own experiences of viewing public health mass media campaigns. Panel members were not convinced that campaigns alone can change health behaviours but did agree that memorable campaigns help build knowledge and awareness around the benefits of taking up health behaviours (i.e. physical exercise) or modifying harmful behaviours (i.e. smoking cessation). They also agreed that campaigns, if well resourced, designed and sustained, can help change social norms around some behaviours (such as condom use to promote sexual health or promote compliance with smoke-free legislation).

One challenge we encountered was in discussing emerging findings with groups other than our public engagement panels. The research team were focused on trying to complete the literature reviews in the face of a large volume of material and had limited time to prepare interim finding briefs, particularly when it became clear how complex the findings of the literature were and that clear directions of effect or impact on key outcomes were difficult to distil into simple summaries. We did approach both CLAHRCs to see if we could discuss review progress at CLAHRC public engagement or planning meetings but we were not able to secure appropriate slots at these meetings and CLAHRC colleagues felt that final outputs from the study might be more appropriate for dissemination. In addition, owing to limited research team time we were not able to engage one youth organisation, Young Scot, in discussing interim findings and as a result of this public engagement activity not taking place we had an underspend (now returned to NIHR) in our public engagement budget. Instead, we were able to involve young people in discussing findings from our final report through a separate organisation (City of Edinburgh Council), as set out in the following section, and this proved very valuable.

Therefore, a primary focus for our stakeholder engagement was end-of-study dissemination and discussion and this is described in the following sections.

Interpreting findings

Once findings from the study were available, the research team invested considerable time and effort in organising a national event to discuss and help interpret results as well as a youth engagement meeting. Each of these events is described here.

End-of-study event

On 28 September 2017, an end-of-study event was hosted in the conference centre at the Iris Murdoch Building, University of Stirling. A series of presentations on the project's background, methodology and results was given by the research team, which represented all the academic teams involved (University College London and the Universities of Nottingham, Glasgow and Stirling). In addition to sharing the findings of the review, the purpose of the event was to discuss the findings with interested stakeholders and experts to identify strengths and limitations of the evidence, to identify implications for commissioning/using mass media campaigns and to identify recommendations for future research. The event was also intended to inform the final report for the study.

An open invitation (see flyer in *Appendix 9*) was issued to relevant policy and practice networks in the UK. Personal invitations were also sent to the study advisory group and key organisations that design and deliver mass media campaigns for public health, such as Public Health England and the Scottish Government. Forty-nine delegates attended the event. These included representatives from local and national charities and advertising agencies, NHS staff, civil servants, clinical academics, public health and marketing researchers, research students and the PPI representative for the study. Delegates had a range of experience, from a deputy director of a Scottish Government department to master's students. There was also representation from across the UK: attendees had travelled from Northern Ireland, Orkney, Shetland, the north-east and north-west of England and London, in addition to those from other UK regions.

The event included a series of presentations from the research team on all the elements of the study. The PI opened the day and began by showing a series of videos of past mass media public health campaigns (*Box 4*). Presentations of study findings were then followed by question-and-answer sessions and small-group discussions with feedback to the room (see the event agenda in *Appendix 10*). Both the event's presenters and attendees were encouraged to share slides and views via social media.

Key points raised among those attending related to a range of themes. Some of these focused on the limitations of the evidence our study identified. Overall, delegates had expected the evidence on the effectiveness of mass media campaigns to be more conclusive. There was a general perception, particularly among those involved in planning or delivering services or promoting public health interventions, that tobacco control mass media in general was highly effective and cost-effective and that this might be the case for mass media on other public health topics. Our review did find that tobacco control campaigns can be effective but this varied based on the type, duration and content of the campaign. Evidence for campaigns on other behaviours was also mixed and in some cases very limited. This challenged the views of some delegates and meant that some of the questions and discussion at the event were not straightforward.

Delegates had a range of questions and useful feedback on the limitations of our reviews and the evidence in general; for example, they discussed the parameters of our review of systematic reviews, the changing media landscape and how this might affect the available evidence, the time lag between campaigns and evaluations being published and the fact that the results of many campaigns, particularly at a regional level, are not captured in the peer-reviewed literature. Attendees also reflected on their own experience (in both research and practice) compared with the review evidence. This included issues to do with fitting mass media campaigns into wider political messages, the fact that diet and nutrition campaigns can come from commercial or industry sources (in contrast to the tobacco industry, which is not permitted to conduct marketing in the UK) and also that commercial advertising involves large budgets, which it is difficult for public health campaigns to counteract (alcohol advertising was highlighted as a particular example). There are also limited available resources for public health campaign rather than research around it. Limited resources also result in difficult choices being made around the medium of communication, with a more recent focus just on social marketing or online campaigns. The literature identified by the study had limited evidence on campaigns run via digital media only, and evaluating these should be a priority for the future.

Discussions also focused on why the evidence differs between health topics; for example, for some health behaviours, it can be more difficult to define what the 'message' should be. Those planning campaigns may favour positive rather than fear-based messaging, but questions remain about which is more effective. With limited budgets, how should campaigns be targeted? The evidence is unclear for campaigns aiming to reach particular population groups. Some of the evidence in our review suggests that a whole-population

BOX 4 Previous UK televised (and online video) mass media public health campaigns

- HEBS (1995): Gavin Hastings 'Did you know that walking a mile ...'.
- HEBS (1997): The Lifesaver 'You can save a life. Your own'.
- Central Office of Information and the Department of Transport (1996): Christmas anti drink-drive: accident-scarred woman at mirror.
- HEBS (c. 1998): 'Night out', Think About It 'You spend ages thinking about what you put on your body, how long do you spend thinking about what you put in it?'.
- NHS Smokefree (2007): Hooked (fish-hook).
- NHS (2005): Family and friends watching TV 'Secondhand smoke is a killer'.
- This Girl Can and the National Lottery (2017): 'Phenomenal Woman'.

HEBS, Health Education Board for Scotland (now NHS Health Scotland).

approach may be desirable, but again this has cost implications. Finally, delegates discussed how indicative evidence identified in our reviews suggests that campaigns focused on increasing healthy behaviours may be more appealing or effective than those focused on reducing unhealthy behaviours. This may be influenced by some of the unhealthy behaviours involving dependence-forming products including tobacco, alcohol and illegal drugs and using mass media to change behaviour around these may be particularly challenging. The insights and suggestions raised by delegates have helped inform how we have approached key sections of this final report and have directly informed how we describe the context and implications of our findings.

Engagement with young people

Two members of the research team (Professor Linda Bauld and Dr Srinivasa Vittal Katikireddi) met with 15 young people on 29 September 2017 to discuss the findings of the study and the logic model that had been developed to inform the research. The meeting took place in a City of Edinburgh Council leisure facility: the Royal Commonwealth Pool, Edinburgh. The young people were attending a youth club that provides access to gym and pool facilities at the venue along with snacks, board games and art materials; it is held every Friday evening during term. The club is known as 'Open All Hours' and is funded by City of Edinburgh Council in partnership with Edinburgh Leisure. Research team attendance at the club was made possible by Laurene Edgar, a youth work organiser, whom Dr Katikireddi contacted after obtaining her contact details from a member of the study advisory group.

The researchers met with two separate groups of young people between the ages of 11 and 15 years. In the first group there were six boys and two girls, and in the second group there were seven girls. The researchers showed some examples of public health mass media campaigns on a television screen connected to a laptop. These ranged from television campaigns on physical activity, alcohol and chronic disease prevention from the early 1990s to slightly more recent NHS campaigns on smoking cessation and second-hand smoke from around 2005–7 and concluded with a current online video of the 'This Girl Can' physical activity campaign funded by the National Lottery. Young people had mixed views about the advertisements, perhaps preferring more contemporary examples, and just one or two of them recognised the 'This Girl Can' film.

The researchers then asked the young people to note down on paper what they thought constituted a 'good' or 'appealing' advertisement. Some of the main suggestions are included in *Box 5*.

BOX 5 What makes a good health promotion advertisement? Young people's suggestions

- Music.
- Strong colours.
- Something unusual or strange that makes you notice.
- Cartoons.
- Featuring normal/real people.
- Outdoor/green areas.
- Before-and-after images of the same person.
- Attractive people.
- People doing silly things.
- Showing what needs to be changed (i.e. smoking, drinking).
- Logos that people recognise.
- Bright, positive images.
- Featuring a celebrity.
- Humour.
- Making scientific information simple.
- Not too long a short advertisement.
- Words on the screen as well as spoken.

With the first group (which spent slightly longer discussing the campaigns than did the second group) the researchers also distributed copies of the study logic model with the details of the model removed and just the headings showing. The researchers explained the purpose of the model and the young people then wrote down some of the elements they thought might connect a public health advertisement with short-term, medium-term and longer term outcomes.

They were able to describe in some detail the key 'inputs' needed for a mass media campaign, including funding, staffing, equipment, ideas and production. They were also adept at identifying key activities after inputs were secured, including where advertisements or other forms of marketing should be placed (television, social media, YouTube, etc.) and how the public and others should be informed about the release of a campaign. They were less sure about the pathway after that between people viewing an advertisement or other campaign output and longer term outcomes. They articulated very clearly what the ideal behavioural outcomes would be in terms of reducing harmful behaviours (stopping smoking and being less sedentary) or increasing healthy behaviours (eating a more balanced diet and being more physically active). They also understood that these behavioural outcomes would be linked to longer life or reducing the risk of chronic diseases such as cancer. However, unsurprisingly, the mechanisms for change between viewing a mass media campaign and possible behaviour change were much more difficult for them to describe.

Despite this, the concept of the logic model and how inputs and activities could be linked to longer term outcomes was something that appeared to resonate with them and supports the concept of the logic model approach. Their notes also illustrate how an unappealing or perhaps not well-sustained campaign could be ignored and might make little difference. They also talked about how young people could view a campaign (e.g. on second-hand smoke) and discuss behaviour change with parents or carers. One girl in the second group gave examples of a friend who had seen campaigns about the harms of second-hand smoke exposure and talked to both her parents about their smoking and smoking cessation.

The discussions with these young people were informative at the stage when the team was drafting the final report for the study and their views have been useful in assisting us to write the discussion section of the report, the further description of the logic model and our summary of findings.

Chapter 7 Discussion and conclusions

The aim of this study was to provide the NHS, local authorities, government and other organisations with evidence on the effective use of mass media to communicate public health messages. We conducted four reviews underpinned by a logic model of how mass media campaigns influence behaviour. These were:

- A review of existing systematic reviews (review A). This comprised a review of 36 English-language systematic reviews published between January 2000 and January 2016 on the effectiveness of mass media campaigns across six health topics. We identified 12 reviews of mass media addressing tobacco use, nine addressing sexual health, seven addressing physical activity and three addressing illicit drug use, with five reviews addressing 'mixed topics' (i.e. more than one of our six health topics). Despite none of the reviews meeting our inclusion criteria for alcohol use or diet mass media interventions, studies evaluating campaigns targeting alcohol or diet were included in four mixed-heath-topic reviews. Findings from this review are presented in *Chapters 2* and *5*.
- 2. A review of primary studies examining alcohol mass media campaigns (review B). This was conducted because review A found no reviews specifically addressing alcohol and limited evidence relating to alcohol in the reviews covering mixed topics. The parameters for the review were English-language primary studies (published up to July 2016) that assessed the effectiveness of mass media public health campaigns to reduce alcohol consumption and related harms. Studies examining drink driving mass media interventions and college campus campaigns were excluded. Findings from this review, which included 24 studies, are presented in *Chapter 3*.
- 3. A rapid review of cost-effectiveness evidence (review C). This involved a rapid review of 13 systematic and seven non-systematic reviews, published between January 2000 and January 2017, which assessed economic studies that evaluated both the costs and benefits of mass media campaigns for any of our six health topics. Findings from this review are presented in *Chapter 4*.
- 4. A review of primary studies of mass media campaigns conducted in the UK and published between January 2011 and September 2016 (review D). The main aim of this review was to provide additional, UK-relevant evidence and evidence on new media to complement evidence from review A regarding campaign characteristics that might be associated with effectiveness. Studies were eligible for inclusion in this review if the paper was published in or after 2011 and the study was conducted in the UK; multicountry studies were eligible if findings for the UK were reported separately. The campaigns had to address one of our six health topics. Findings from this review, which included 25 studies, are presented in *Chapter 5*.

In addition, we conducted stakeholder engagement work, which is described in Chapter 6.

In the remainder of this chapter, we aim to synthesise our findings across the different chapters, to reflect on implications for our logic model and gaps in the evidence and to identify pointers for future research.

How effective are mass media campaigns?

We addressed this question with three reviews: a review of 36 systematic reviews (review A), a review of 24 primary studies on alcohol mass media campaigns (review B) and a cost-effectiveness review of 20 reviews and systematic reviews (review C).

Review A, which included 36 systematic reviews, brought together evidence on the impact of mass media campaigns on health behaviours (including alcohol use, illicit substance use, diet, physical activity, sexual and reproductive health and smoking cessation and prevention) for the first time. Overall, the evidence base for the effectiveness of mass media for behaviour change is mixed. First, the amount of evidence varies across health topics, with most evidence relating to campaigns addressing tobacco use, followed by

sexual health and physical activity. The strength of evidence from reviews also varies. Using a modified GRADE approach,^{33,34} we found moderate evidence for the positive effects of mass media campaigns on reducing sedentary behaviour and sexual health-related behaviours such as condom use. Low-certainty evidence for positive impacts on diet was found, although the overall volume of evidence on diet was very limited. The impact of the mass media on tobacco use and physical activity, such as stair use and brisk walking, was mixed, but with low-certainty evidence in both cases. In contrast, the available and again low-certainty evidence on illicit drugs suggests no impact of mass media. All reviews found considerable variation between individual studies as described in a meta-analysis or narrative synthesis, suggesting that variations in implementation of the campaign and evaluation methods may be important.

For treatment-seeking behaviours, there was low-certainty evidence that mass media campaigns can help increase the use of sexual health clinics or services. Whether or not media campaigns can prompt calls to telephone quitlines for smoking cessation has been fairly extensively studied in five reviews. Overall, the direction of effect looks positive, with campaigns serving to prompt calls to quitlines, but variation in results and the quality of studies was identified – therefore, there is only moderate certainty in the strength of this finding. A recent study examining the impact of Scottish tobacco control mass media campaigns (2003–12) found a cumulative increase in calls to a quitline, sustained for 6 months.¹⁶¹ This is further evidence of a positive direction of effect; however, the study found no impact on NRT prescription volumes.

Evidence on distal outcomes (reduction in illnesses, improved population health, reduced health service usage, societal change, policy change and impact on inequalities) was also examined, and little evidence was found. However, distal outcomes can be defined in different ways to those adopted in our logic model, and can, for example, include denormalisation and longer term shifts in public attitudes regarding the acceptability of a behaviour. One systematic review noted that:

There is evidence of good quality (1&2+, C), which shows an effect of mass media interventions on attitudes towards smoking and intentions to smoke among young people under 25 years.
 © NICE 2008. A Review of the Effectiveness of Mass Media Interventions Which Both Encourage Quit Attempts and Reinforce Current and Recent Attempts to Quit Smoking.⁴³ Available from www.nice. org.uk/guidance/ph10/evidence/a-review-of-the-effectiveness-of-mass-media-interventions-which-both-encourage-quit-attempts-and-reinforce-current-and-recent-attempts-to-quit-smoking-pdf-369842079. This suggests that mass media programmes may have contributed to the denormalisation of smoking among young people.

Changes in health behaviour are the ideal outcome of mass media health campaigns. However, theories of health behaviour change are generally based on an assumption that behaviour change happens incrementally or via changes in mediating variables such as changes in knowledge, attitudes, self-efficacy and intentions.^{7,162,163} A more realistic assessment of the value and effectiveness of mass media campaigns takes into account the impact of such campaigns not only on behaviour but also on these mediating variables. Our review of reviews examined evidence regarding indirect behavioural outcomes (intentions to engage in, reduce or desist from unhealthy behaviours or to engage in healthy behaviours) and social cognitive outcomes (awareness, knowledge, attitudes, beliefs, norms and self-efficacy).

In the 15 reviews examining the impact of mass media campaigns on knowledge and awareness, there was evidence of positive impacts on increased knowledge and awareness in relation to sexual health, such as knowledge of HIV prevention, contraception and sexual health services. Positive results were also reported for increased knowledge and awareness of tobacco risks and services to help quit, increased knowledge and awareness for diet and for physical activity. There was mixed evidence regarding the impact on knowledge and awareness of illicit drug use. In the seven reviews examining the impact of mass

media campaigns on intentions, there was generally positive evidence of impacts on intention to increase physical activity (although from a review with a high risk of bias), and there was some evidence of positive impacts on intention to quit smoking. There was mixed evidence regarding intention to stop the use of illicit drugs and to use contraception. In 10 reviews reporting on attitudes, beliefs and self-efficacy, there was evidence of positive impacts on beliefs about risk of pregnancy and the use of condoms, from reviews of studies in low-income countries. There was mixed evidence of the impact on attitudes towards illicit drug use and tobacco. A mixed-topic review that included studies from the UK reported positive results on attitudes towards reducing tobacco use and increasing physical activity.

Some previous reviews and meta-analyses have reported stronger evidence that media health campaigns can produce positive effects on behaviour change, but have also suggested that this differs with the type of behaviour. Anker et al., 164 in a meta-analysis, found a significant effect for the use of mass mediated health campaigns on behaviour across 51 primary studies, but the size and significance of campaign effects varied across target behaviours, with campaigns working best for increased transport safety and also better than controls for cardiovascular disease, physical activity and nutrition. Wakefield et al.6 reviewed the outcomes of mass media campaigns in the context of a wide range of health-risk behaviours (e.g. use of tobacco, alcohol, other drugs, heart disease risk factors, sex-related behaviours, road safety, cancer screening and prevention, child survival and organ or blood donation), and concluded that mass media campaigns can produce positive changes or prevent negative changes in health-related behaviours. They concluded that the success of mass media campaigns was greater when the target behaviour was one-off or episodic (e.g. screening, vaccination and children's aspirin use) rather than habitual or ongoing (e.g. food choices, sun exposure and physical activity). Many of these one-off behaviours were not included in our review, and our focus on lifestyle behaviours may have contributed to the overall weaker evidence of success in actual behaviour change as opposed to its mediating factors. Of the behaviours that were included in our review, the strongest evidence of success in behaviour change was seen for reducing sedentary behaviour and improving sexual health behaviour (e.g. wearing a condom). The Anker et al.¹⁶⁴ meta-analysis identified a weighted mean effect size of 0.05 for effects of campaigns on behaviour change, and proposed that this 5% benchmark could provide a standard against which future media intervention studies could assess success. In the reviews that we identified, when there were sizes of effect for campaigns to reduce sedentary behaviour or increase physical activity, these generally met or exceeded this benchmark for success, and those for condom use tended to produce somewhat greater effects. One interpretation of these findings is that media campaigns are most successful when the behavioural goal is simple, a conclusion also drawn in an NHS Health Development Agency report from 2004.165 It might be anticipated that the more complex the behaviour change (e.g. if it involves a component of addiction as with tobacco or illicit drugs), the more back-up is required to supplement the mass media campaign. Although our review was limited in its evaluation of contextual moderators, some of the included reviews (e.g. the Cochrane Database Systematic Review of tobacco control campaigns²⁷) conclude that these can be important in the context of wider or multiple interventions, such as a comprehensive tobacco control programme. This should include the appropriate support services. Looking across health behaviours, Wakefield et al.⁶ highlight that concurrent availability of and access to key services and products are crucial to persuade individuals motivated by media messages to act on them.

A further aspect of context is the prevalence of the behaviour in the population. Naugle and Hornik,¹⁶⁶ in reviewing the literature on child survival in low- and middle-income countries, highlight that, for mass media campaign effects to be detected, there 'must be room to move the population on the target behaviour'. It is possible that this contributes to the positive outcomes of some mass media sexual health campaigns in non-OECD countries where baseline rates of condom use were low.

We found additional evidence regarding the effectiveness of mass media campaigns in review B. Our systematic review of primary studies of mass media campaigns targeting alcohol was the first comprehensive synthesis of evidence from such campaigns. The overall quality of the evidence base was low, predominantly owing to the use of weak study designs, risk of participant selection bias and self-reported outcome data.

Overall, we found very limited evidence that campaigns were associated with reductions in alcohol consumption, although the majority of reports did not state that reducing consumption had been an aim of the campaign. Most campaigns had aims such as improving knowledge of, awareness of and communication about alcohol. Despite this, it is likely that reducing consumption was an implicit long-term aim of all campaigns, as they all targeted outcomes that can be considered precursors to consumption within our logic model. Longer term evaluations following repeated exposure to campaign messages may be needed to detect changes in consumption, of which we found few. There are important social, cultural and environmental barriers to alcohol behaviour change, such as widespread alcohol advertising and pro-alcohol cultural norms. This provides a challenging context that contrasts with tobacco, for example, for which advertising is highly restricted and norms are antismoking. Other reviews have concluded that social norms interventions were ineffective at reducing alcohol consumption by university and college students and that reductions in drink driving could not be attributed to mass media campaigns alone.^{77,167} Our findings add to this evidence and are consistent with the conclusion of Snyder *et al.*¹⁶⁸ that mass media campaigns should have modest expectations of effect on health behaviour. Alcohol campaigns in particular face a number of competing forces that may limit their effectiveness at reducing consumption.

There was some evidence in review B, from mainly weak-quality studies, that alcohol mass media campaigns were associated with increases in information-seeking and treatment-seeking behaviour. There were mixed findings regarding other proximal outcomes, such as attitudes, beliefs, intention and self-efficacy. Mass media campaigns face a number of challenges in terms of these sorts of outcomes: they may be perceived to be aimed only at very heavy drinkers (meaning that many in the population disregard them as not relevant) and can lack a clear call to action, typically advising limiting units consumed rather than abstinence. There was mixed evidence of interaction with campaigns and discussion or onward transmission of campaign messages, from mostly weak-quality studies. More encouragingly, studies reported high levels of campaign recall, and evidence that campaigns were associated with increases in knowledge about alcohol, especially where it had initially been low. This is a key finding and perhaps indicates where mass media messages about alcohol are currently best targeted to achieve change. This is particularly important given that knowledge about alcohol unit consumption guidelines and the health risks associated with alcohol consumption is reported to be very low.¹⁶⁹

Our searches for published English-language evaluations with no time limit applied produced only 24 campaigns (in July 2016). In comparison, a content analysis study by Dunstone *et al.*¹⁷⁰ identified 72 English-language campaigns conducted between 2006 and 2014. This suggests that a large proportion of alcohol campaigns have not been evaluated and published. A greater investment in alcohol campaign evaluation is needed in order to better understand its effectiveness. We found only two reports of campaigns that used online or social media as a primary channel.^{86,102} An important challenge for future research is therefore to evaluate the effectiveness of newer digital media channels to communicate alcohol health messages.

Regarding the cost-effectiveness of mass media campaigns, review C examined evidence from 20 systematic and non-systematic reviews (published between January 2000 and January 2017), reporting on 15 individual primary studies. Included reviews were required to assess economic studies that evaluated both costs and benefits of mass media campaigns (i.e. full economic evaluations, not just intervention costs or cost savings). Taken together, the reviews and the findings of the primary studies within the reviews provided moderate evidence that tobacco control mass media campaigns can be cost-effective. There was weak evidence in relation to diet campaigns (restricted to a campaign seeking to reduce salt intake) and physical activity, and no evidence in relation to the cost-effectiveness of sexual health campaigns, despite efforts to identify such evidence in systematic reviews.

Recent work by Marsh *et al.*¹⁷¹ on how to prioritise investments in public health ranked 14 intervention types in order of cost-effectiveness (cost per quality-adjusted life-year gained). Increasing alcohol and tobacco tax by 5% topped the list, national mass media campaigns for smoking were third in the list and national mass media campaigns for obesity were fifth in the list. However, overall, evidence on the cost-effectiveness of mass media campaigns was extremely limited for all health behaviours except

smoking. Regarding smoking, the studies in the included reviews generally found tobacco mass media campaigns to be cost-effective. However, the fact that only effective interventions tend to be taken forward to an economic evaluation, and hence the potential for bias in reviews on this topic, should be taken into account.

How effective are mass media campaigns with different target populations?

The majority of the 36 reviews included in review A provided evidence on whether the effects of mass media campaigns were similar or different across subpopulations. Our analysis of this evidence found that mass media campaigns may reach and affect groups in the population differently. Although age differences were not always measured, reviews of tobacco and illicit drug campaigns found that mass media appeared to be more effective for young people, and particularly for younger children rather than for older teenagers. There was modest evidence that mass media outcomes for tobacco, sexual health and physical activity do not differ by sex and no clear consistent evidence was found for ethnicity or socioeconomic status. Looking at baseline measures of health behaviours, physical activity campaigns may be more effective for less active or obese people than for others.

This paucity of good-quality evidence on the differential effects of campaigns on behaviour across different population groups is a concern. It has been suggested that health promotion interventions might increase rather than decrease inequalities, and particularly socioeconomic inequalities, in health, because messages and interventions may have a differential take-up and success across different social class groups.^{37,40,43} The reviews included in review A, all based on tobacco control campaigns in contexts in which there are marked inequalities in smoking prevalence and morbidity, provide mixed evidence regarding whether or not effects on behavioural outcomes vary across socioeconomic groups. Nevertheless, the evidence is more consistent that interventions will be more effective if appropriately developed and targeted to reach the intended audience, and this will be important to ensure that campaigns work to reduce inequality. We are aware of an ongoing systematic review on targeted mass media interventions promoting healthy behaviours to reduce risk of NCDs in adults from ethnic minority groups.¹⁷²

Evidence for the greater effectiveness of campaigns among the young, mostly based on tobacco control campaigns, is consistent with much of the communications literature. Advertising is well known to work effectively in children and young people,^{173,174} and advertisers seek to use this to establish behaviour and brand preference at an early age. The evidence from this review suggests that anti-tobacco mass media messages can also be effective in the young, and that the impact may be greater on uptake of smoking than on cessation in adults, possibly because it is simpler to change behaviour before the onset of addiction.

What characteristics of mass media campaigns are associated with effectiveness?

We sought to identify characteristics of mass media campaigns that may be associated with effectiveness, drawing on evidence from the review of reviews (review A) and from the additional review of UK primary studies (review D). Overall, there was limited evidence on the contribution of media campaign characteristics to effectiveness, with only a small number of reviews and studies containing statistical analyses to assess the impact of different characteristics.

Across all the reviews included in review A, there was little evidence regarding the role that theory may play in campaign effectiveness, with most reviews simply listing which theories, if any, had been referred to in intervention studies. There was limited evidence regarding media channel as a potential moderator of effectiveness in three reviews, with findings varying depending on the types and topics of campaigns, and

[©] Queen's Printer and Controller of HMSO 2019. This work was produced by Stead *et al.* under the terms of a commissioning contract issued by the Secretary of State for Health and Social Care. mostly having limited relevance to the contemporary UK context. Longer intervention duration or greater intensity/exposure were found to be related to effectiveness in several reviews, with most of the evidence relating to tobacco and to a lesser extent sexual health campaigns; however, there was little clear guidance or consensus on how long or intense campaigns should be to produce effects. One of the reviews noted a recommendation from the US Centers for Disease Control and Prevention that advertisements should be aired for a minimum of 6 months to affect awareness and up to 24 months to have an impact on behaviours, and should be aired as frequently as possible.⁴⁴

Lack of formal statistical analysis in the reviews included in review A meant that clear conclusions about the type of messaging content that is most effective could not be drawn. There was evidence from the reviews that social norms campaigns and negative (i.e. hard-hitting messages on health consequences) messaging could change behaviour, but little evidence regarding whether or not these were more effective than other approaches. The reviews included in review A indicated that targeting can be effective, suggesting that messages needed to be appropriate to the target audience, taking into account a range of characteristics including age, sex, culture and level of engagement in the activity. There was evidence to suggest that targeting specific subgroups such as the young could be effective, but with caution to avoid patronising or stereotyping. There was no evidence from the reviews on the scale of campaign (i.e. whether it was implemented at a national, regional or local level) acting as a moderator of effectiveness. Regarding source, there was evidence that tobacco industry-sponsored campaigns were not effective.

The UK primary studies that we examined in review D for evidence regarding campaign characteristics were mostly concerned with tobacco, plus a small number of physical activity interventions. This limited the value of the evidence for other health behaviour topics, but an advantage of examining this evidence was that all the studies were relevant to the UK context, and when examining the role of message the primary studies examined a wider range of message types than did the reviews. The evidence from the UK primary studies in review D suggested that positive messages may also be important, with both positive and negative messages affecting smoking behaviour. Regarding messages for physical activity, there was mixed evidence regarding effective messages for poster campaigns promoting stair use. Evidence from the primary studies included in review D regarding intervention duration or intensity/exposure as moderators of effectiveness was consistent with that from the reviews, generally finding that more sustained and greater intensity campaigns were more effective. There was limited evidence that government and charity campaigns may be more effective than those from pharmaceutical companies (e.g. NRT manufacturers). Only one study compared different media channels within the same study (a comparison of audience engagement through different social media channels). As with review A, there was little evidence regarding the use of theory as a potential moderator of campaign effectiveness, and no evidence regarding scale as a moderator of effectiveness; the latter was not surprising, as any statistical comparison of the effect of scale (e.g. national vs. local-level campaigns) is more likely to happen at a review level than in a primary study, although none of our included reviews examined this.

Evidence from other literature regarding the characteristics of mass media campaigns associated with effectiveness is limited. A recent review by the US Centers for Disease Control and Prevention¹⁷⁵ of physical activity mass media campaign design suggested that campaign success was more likely if a number of campaign principles (formative research, audience segmentation, message design, channel placement, process evaluation and theory-based) were used as part of campaign design and planning. Some of these principles were tested in a recent meta-analysis, published while our study was ongoing.¹⁶⁴ Five campaign design principles thought to be associated with effectiveness were examined in the meta-analysis: (1) the use of formative research to help develop messages and campaign content, (2) the use of theory, (3) message, (4) channel and (5) 'environmental supplements', in this case defined as efforts to educate health-care providers and supplementary materials/services (such as free condoms or reduced-cost screening). The study differed from ours in that it reviewed primary studies rather than reviews, and included a wider range of health topics. In total, data from 63 articles were included in the meta-analysis, which, overall, found little evidence that principles of effective campaign design explained a significant

amount of heterogeneity in effect sizes. Some results were described by the authors as 'puzzling', such as findings that the use of formative research significantly reduced effects on behaviour change or that there was no improvement in outcomes when campaigns were theory driven, or that the use of more channels to disseminate messages was associated with lower effects on knowledge. The authors suggested that some inconsistent or unexpected findings may have been explained by small numbers of studies in some of the moderator analyses, by confounding by multiple moderators, or simply by studies failing to report certain moderators.¹⁶⁴

A recent review of mass media tobacco campaigns that focused on the relative effectiveness of different campaign characteristics found that young people were more likely to recall and think about advertising that includes personal testimonials, a surprising narrative, and intense images, sound and editing; however, it found mixed evidence regarding use of health consequences messages, a second-hand smoke theme or a social norms theme.¹⁷⁶ Since commencing our own review of systematic reviews, the Cochrane Database Systematic Review on mass media interventions for preventing smoking in young people has been updated,^{35,177} adding one more RCT to the evidence base but not changing the overall findings. Regarding mass media channels used in this updated review, the authors note that the 'inclusion of only two studies from the last 10 years is concerning, particularly considering the rising use of social media among youth. More high-quality studies are needed'.¹⁷⁷

What are the implications for our logic model?

Our four reviews indicate that there is a lack of theory employed in the development of mass media campaigns and their evaluation. In this respect, our logic model provides a useful starting point for researchers, practitioners and commissioners planning future campaigns. The lack of theory underpinning current campaigns suggests a greater need to recognise the importance of utilising existing theories, concepts and logic models and to apply this knowledge in a systematic manner to the processes of campaign planning, development, implementation and evaluation. In particular, there is a need for future campaigns to be based on a deeper understanding of the fundamental principles of communication, persuasion and changing social norms, as well as an appreciation of the interplay between communication theories, behaviour change theories and the wider sociopolitical context in which mass media campaigns often operate. Indeed, mass media campaigns rarely operate in a vacuum, and our logic model would be further strengthened by empirical research that better explores the interplay between the political and mass media campaigns' agenda-setting functions. Such insights would aim to explore the opportunities and challenges encountered in attempting to explore causal pathways and disentangling the effects of campaign activities from external influences – including political influences. Such research would develop better understanding of the complexity of mass media campaigns in the process of health improvement. McCoy and Hargie¹⁷⁸ echo this when referring to the prerequisite of effective evaluation as the deep understanding of its 'nature, purposes and concepts'. Mass media campaigns can, if developed in a strategic way and informed by principles and theories of effective communication, be successful in conveying health messages to large sections of the population at a relatively low cost and, for this reason, are a useful tool to promote health. However, it is imperative to invest in research that develops a strong evidence base for understanding what works and in what context in order to maximise the effectiveness of mass media interventions.

The original logic model we developed (see *Figure 1*) did not adequately reflect the body of literature we found from the review of systematic reviews. The outcomes we identified at the outset were not discussed as proximal, intermediate or distal in the papers, which tended to refer to them as outcomes without distinguishing between them. In some ways this is understandable because behaviour change is rarely a linear affair, as many behaviour change theories suggest a more iterative process. Therefore, we conclude that, although the terms 'proximal', 'intermediate' and 'distal' were not useful labels in the data extraction tool, they may be useful in thinking through how to better identify the evaluation outcomes of an intervention.

Strengths and limitations of the study

Strengths

This review adds value to the current literature on mass media interventions by bringing together a large amount of evidence for a variety of health topics and enabled a comparison between them. It combined the breadth that is offered when looking across review-level evidence with the depth obtainable from examining individual primary studies. In response to frequent calls for in-depth analysis of how campaigns work (e.g. Cassidy *et al.*¹⁷⁹), it examined intervention characteristics that are associated with effectiveness. The review has particular relevance to the UK context, and we sought feedback from stakeholders to assess its usefulness.

Methodological limitations

We were unable to conduct statistical synthesis owing to the considerable heterogeneity across the studies. This makes it difficult to draw firm explanatory conclusions about the causes of the variability in results, noted by Ferri *et al.*⁶² among others. In the review of reviews, some of the primary studies were published in the 1980s and 1990s and, thus, were discussing technologies that are no longer relevant. The searches for review A, the review of reviews, were conducted in January 2016. Searches for the subsequent reviews were conducted later (up to January 2017 for review C), reflecting the sequential nature of the project. Although offering a breadth that would have been unachievable if only primary studies had been examined, the focus on reviews meant that, at times, we lacked contextual and intervention details, and there may have been some overlap in studies between reviews. It was difficult to assess bias within the existing reviews because this would have entailed redoing their analyses. Inevitably, our results are limited by the quality of the primary studies, and reflect a publication bias in which weaker campaigns are rarely evaluated, and interventions with poor results are less likely to be written up and published.¹⁶⁶

As noted above, there are a number of issues involved in assessing the cost-effectiveness of mass media campaigns. Data are generally limited, with few studies; this is the case even regarding tobacco use, the health topic that tends to be most frequently examined in mass media studies and reviews. Part of the reason for the lack of studies is likely to be the challenges associated with extrapolating short-term effects (e.g. increase in quit attempts) to long-term costs and outcomes, which requires expertise in mathematical modelling. The evidence is also likely to be biased, with ineffective evaluations being unlikely to undergo economic evaluation, thereby running the risk that the intervention under examination is likely to look more cost-effective than it is on average. Finally, approaches to the synthesis of economic evidence are still being developed. Cost-effectiveness analyses, in particular, are very context specific, and it is challenging to conduct systematic reviews of such studies while maintaining global relevance.

Limitations in scope/definitions of our study

Although the study was wide-ranging, necessary parameters in terms of scope and how mass media campaigns were defined meant that there were inevitable gaps in the evidence we could review. We focused on six topics relating to preventable risk factors for disease: alcohol use, diet, illicit substance use, physical activity, sexual and reproductive health and smoking. The focus on disease prevention meant that campaigns addressing related behaviours but with a different focus were excluded: we did not include alcohol campaigns whose main focus was drink driving. Mass media campaigns seeking to raise awareness, counter stigma and encourage help-seeking behaviour in relation to mental health issues were excluded, as were road safety campaigns (e.g. targeting speeding or seat belt use) and campaigns encouraging skin cancer protection behaviour. Mass media campaigns that sought to encourage participation in screening programmes were excluded, although campaigns that encouraged condom use and HIV/AIDS testing) were included because of the behaviour component. Because of our focus on population behaviour change, we excluded evidence relating to the use of the media in a media advocacy context, in which news media coverage and other forms of media messages are used to foster public and policy-maker support for policies or legislation to promote health, such as changes in taxation, drink driving laws or restrictions on marketing

activity.^{180–182} Previous research has suggested that media coverage achieved as part of a multifaceted advocacy campaign can be one of the factors leading to successful policy change, although the challenges of demonstrating the particular contribution of media to the outcomes are considerable.¹⁸³

We defined mass media campaigns as the intentional use of any media channel(s) of communication by local, regional and national organisations to influence lifestyle behaviour through largely passive or incidental exposure to media campaigns, rather than largely dependent on active help-seeking (adapted from Wakefield *et al.*⁶ and Bala *et al.*²⁷). We adopted this definition of mass media as it is potentially the most useful for campaign planners seeking an estimate of the effectiveness of campaigns implemented in naturalistic settings that do not require active audience engagement with a given channel to achieve message exposure.¹⁶⁴ However, this meant that certain types of communications-based intervention were excluded. Interventions that require individuals actively to seek out the information (such as websites) or to opt in or sign up (such as SMS/text messaging for smokers trying to quit) would have been excluded because they require active engagement by target populations. Not including these interventions has limited what the review can say about new/digital/interactive media interventions. However, that missing evidence may be limited in itself. A fairly recent scoping review of how digital media (including visual, electronic and online media) are used in the area of public health¹⁸⁴ found that current public health usage is predominantly the 'outmoded approach of "telling and selling" and cast[s] the recipient in an individual and passive role', based on 221 systematic reviews published between 2000 and 2013.

Large multifaceted community interventions that included a media element were included only if it was possible to relate effects to the media component of the campaign. For example, a review of interventions that involved a mass media campaign combined with health-related product distribution was included because the outcomes that related specifically to the mass media were reported and synthesised by the authors.⁶⁹ However, this meant that evidence from reviews such as the Cochrane Database Systematic Reviews of universal multicomponent prevention programmes for alcohol misuse and community interventions for preventing smoking^{76,185} and the 'Change4Life Smart Swaps' intervention study (Wrieden and Levy¹⁸⁶) was not included in our reviews. We are therefore limited in what we can conclude about the extent to which mass media campaigns can interact with other interventions or services to improve health outcomes, which was one of our original objectives. However, our review of reviews found promising evidence regarding the ability of mass media campaigns to stimulate engagement with other services. We found that, overall, media campaigns can prompt calls to telephone quitlines for smoking cessation (although there is only moderate certainty in the strength of this finding). For helping to foster engagement with sexual health clinics or services, there was low-certainty evidence that campaigns can increase use of such services.

In examining characteristics of mass media campaigns that may be associated with effectiveness, we focused on campaign components that featured in the 'Activities' box of our logic model. We did not examine mass media campaign 'Inputs', which in our logic model included resources, staff, expertise/skills, technology and materials, although the full economic evaluation reviews in our rapid review of cost-effectiveness (review C) would have taken into account the upfront costs (resources) of mass media campaigns, when information was reported.

Gaps in the evidence and implications for future research

As noted above, the amount of evidence relating to mass media campaigns varies considerably across different health behaviours. The most commonly studied behaviour, as reflected in the number of existing reviews we found that met our criteria, was tobacco use, followed by sexual health and physical activity. Although there were a relatively large number of reviews of sexual health mass media campaigns, many of the studies in these reviews were conducted in non-OECD countries and so had limited relevance to the UK context. Just three reviews of media campaigns on illicit drugs were identified, and no single review examining the effectiveness of mass media for addressing alcohol use or diet was found, although these

behaviours were addressed in reviews examining multiple health behaviours. We partially addressed this latter gap by conducting the first (to our knowledge) review of mass media campaigns on alcohol use, but were unable, within the time and resources available, to conduct a similar review for mass media campaigns addressing diet. This remains a gap.

In part, the variations in the amount of evidence reflect the amount and nature of activity in each topic area (e.g. several major campaigns on smoking cessation and second-hand smoke in the 1990s/2000s and a decline in mass media campaigns on sexual health in the UK after the 1980s/early 1990s). Another contributory factor to the apparent lack of evidence we found in some health behaviour topic areas is that our definition of mass media campaigns would have excluded media activity implemented and evaluated as part of multicomponent community interventions such as the Department of Health and Social Care's Change4Life public health programme. In other words, the gaps in evidence we found in some areas do not necessarily mean that there has been no mass media activity or that this activity has not been evaluated, but rather that sometimes this mass media activity has taken place in the context of wider multifaceted interventions in which the specific contribution of mass media cannot be examined separately. The challenge of disentangling the contribution of mass media elements from the contribution of other intervention elements, in multifaceted interventions, is recognised elsewhere.^{6,58}

Naugle and Hornik¹⁶⁶ recommend that:

In the future, evaluators should address threats to inference of mass media effects by using unbiased samples, multiple comparison groups across time, levels of exposure, and treatment and control sites, statistical controls and advanced statistical methods, and data triangulation. The written report should reflect the measures taken to mitigate threats to inference. Published evaluations of mass media campaigns should provide detailed information about the campaign, exposure, and the evaluation to permit meta-analyses as the literature base grows.

The moral rights of the named author(s) have been asserted

After starting our reviews of the evidence, we became aware that the evaluation methods for social media and public health mass communication interventions are being appraised as an ongoing registered systematic review.¹⁸⁷

One of our objectives was to assess new or emerging evidence about campaigns employing different types of media, including new media. Overall, we found limited evidence regarding such campaigns. The nature of reviews of reviews is such that newer evidence tends not to be included; in our review of reviews published from 2000 to early 2016 (review A), the years covered by the identified reviews ranged from database inception to January 2015, with the most recent reviews including studies up to 2013. The review of UK primary studies published between 2011 and 2016 (review D) included some more recent evidence relating to interventions using newer media, but this was limited. In part, the limited evidence we found regarding campaigns using newer media reflected our definition of mass media campaigns as those involving incidental exposure, which as noted above would have excluded interventions that required individuals to engage in active information-seeking or to opt in to campaign participation (e.g. joining the Smokefree Facebook community or downloading the Public Health England One You Drinks tracker app). Reviews in this area have suggested that new digital media have the potential to be 'user controlled and shareable', ¹⁸⁸ crucial elements for reaching a large population while at the same time providing interpersonal support to heighten the effects of public health campaigns;¹⁸⁹ and the scoping review of reviews by Clar et al.¹⁸⁴ showed that all six of our health topics are targets of digital media for public health. A review of 10 studies that evaluated the impact of new digital media interventions on adolescents' sexual health found changes in sociocognitive outcomes (although not always in a positive direction), and two interventions showed a reduced risk of sexual initiation among young teenagers.¹⁸⁸

The 'user controlled and shareable' aspects of new/digital media interventions mean that they are not standardised products, and this poses challenges for evaluation. McGloin and Eslami¹⁹⁰ note that 'although web-based, social-media-based and mobile-based studies tend to show positive results for dietary behaviour change, methodologies have yet to be developed that go beyond basic evaluation criteria and move towards true measures of behaviour change'. Guse *et al.*¹⁸⁸ suggest that evaluations using RCTs 'can be laborious, with timelines that are inconsistent with the paces of technology and youth culture'. More research that tests new/social media interventions using rigorous methods, and that compares them with interventions using more traditional media (e.g. Jane *et al.*¹⁹¹), is needed and we note that research into reviewing the evaluation methods for social media interventions is ongoing.¹⁸⁷

Another original objective of our study was to examine the relationship between local, regional and national campaigns and evidence of effectiveness where this exists. Although the reviews included in the review of reviews sometimes noted at what scale included interventions had been implemented (i.e. local, regional or national scale), none of the reviews compared or reflected on scale as a potential moderator of campaign effectiveness. There was similarly no evidence on scale of a campaign as a moderator of effectiveness in the review of UK primary studies; however, it is interesting to note that the review of UK primary studies included studies at both ends of the spectrum, ranging from national whole-population television campaigns on smoking to highly localised poster campaigns promoting stair use in a specific area or building. Future research could explore the potential relationship between scale of campaign and type of health behaviour change in more detail. For example, is physical activity more effectively promoted with a highly localised campaign focusing on physical activity in a particular location, or with a national campaign focusing on physical activity in general, and could highly localised campaigns be used to promote other types of health behaviour than physical activity? For commissioners of campaigns interested in how local/regional and national campaigns can be designed to work synergistically, it may be useful to examine process and other evaluations of campaigns that are designed to be implemented at both national and local/regional levels, such as National No Smoking Day or Dry January.

Chapter 8 Conclusion

This study provides a new synthesis of existing research on the use of mass media to communicate public health messages. Informed by a logic model, the study involved a review of evidence on the effectiveness of mass media campaigns across six health topics that represent the main preventable risk factors for disease morbidity and mortality in developed countries:¹⁵ alcohol use, diet, illicit substance use, physical activity, sexual and reproductive health and tobacco use.

First, we conducted a review of systematic reviews (review A). This was informative and provided a high-level overview of what is known on this topic, including identification of gaps in the evidence. We found no systematic reviews of mass media campaigns specifically addressing alcohol use that met our inclusion criteria, and thus we conducted our own original review on this topic (review B). The overall study also aimed to examine the cost-effectiveness of mass media campaigns for the six health topics of interest, and this was addressed in a third review (review C). The final element of our study involved a systematic review of English-language primary studies of mass media campaigns targeting the same six health topics, conducted recently in the UK (review D). This was conducted to provide additional evidence on campaign characteristics that might be associated with effectiveness that was directly relevant to the current or recent UK context.

Our review of reviews also found no systematic reviews of the effectiveness of mass media campaigns to improve or modify diet. We conducted a scoping search for this, which resulted in > 16,500 references being identified in MEDLINE. Within this study, we did not have the available time or resources to conduct a full, new systematic review on this topic.

Our study had a number of limitations, as described in *Chapter 7*. However, key messages and priorities for future research emerged.

Key findings

First, logic models provide a useful basis for planning and conducting systematic reviews on complex topics such as mass media for public health messages. Our model proved essential in helping us to develop the scope and focus of our reviews, in partnership with stakeholders, and was refined as the study progressed. We hope that our logic model will prove useful to others studying this topic or indeed those designing campaigns and considering what issues to assess or measure in any evaluation.

In addition, a number of systematic reviews of mass media campaigns have been conducted but there is significantly more literature on tobacco control mass media campaigns than on campaigns focusing on other topics, although campaigns on sexual health and physical activity have been evaluated in a number of studies and these findings have been brought together in reviews.

Looking across reviews, the strength of the evidence varies. The impact of the mass media on tobacco use and physical activity is mixed, based on the available literature. There is moderate evidence for the positive effects of mass media campaigns on reducing sedentary behaviour and sexual health. Review-level evidence was of low certainty for the impact of campaigns on illicit drugs.

Mass media campaigns can prompt people to contact or access services (treatment-seeking). There is evidence that tobacco control mass media campaigns can prompt people to call smoking quitlines and some, but more limited, evidence that mass media campaigns can help to increase the use of sexual health clinics or services.

Mass media campaigns on alcohol have been evaluated to a modest degree in the literature. Campaigns can be memorable and can influence knowledge, attitudes and beliefs about drinking, but there is limited evidence that these campaigns can help reduce alcohol consumption.

There is moderate evidence that tobacco control mass media campaigns can be cost-effective. We found almost no data on the cost-effectiveness of mass media campaigns for other health behaviours, and this requires further research.

How effective a mass media campaign is may depend on its characteristics, and we examined this in both review A and review D. Campaigns that run for longer and are more intensive (with people exposed to them more often, for example) are likely to be more effective, based on evidence from tobacco and sexual health campaigns in particular.

Targeting a campaign at different audiences (such as young people) can be effective. Targeted campaigns need to be designed and tested to be appropriate to the target audience taking into account age, sex, culture and level of engagement in the behaviour of interest.

The messages featured in a campaign may also make a difference. We found some evidence in review A that those focusing on 'hard-hitting' (negative) messages, for example, or on shifting social norms, may change behaviour, whereas the UK studies in review D found evidence that campaigns with both positive and negative messages may affect smoking behaviour. However, few direct comparisons of different messages were identified and we also found gaps relating to the use of theory, the type of media channel used and the scale of a campaign (national, regional or local).

Future research

Our study identifies clear priorities for future research. These include the need for a systematic review of mass media campaigns on diet. Evaluations of mass media campaigns need to be rigorous and to include detailed information on the campaign itself, and on target population exposure. In addition, more information is required on the cost-effectiveness of mass media campaigns for public health messages, particularly on topics other than tobacco. Researchers should aim to include cost data and ideally assess cost-effectiveness in future studies. We identified some findings on new media (see *Chapter 5*), but the data were mixed and it was difficult to offer firm conclusions in this area, at least partially because of the time lag between campaigns being run and evaluations being conducted and published.

More studies and reviews on the effectiveness of new-media (including digital and social media) campaigns are needed. In addition, and although very difficult to achieve, a separate study could be commissioned to examine the specific contribution of mass media campaigns when delivered as part of multicomponent community interventions. In reality, mass media campaigns do not exist in isolation but are often designed to complement other public health programmes or interventions, but unpicking their 'independent' effect in this context may be very difficult in practice. Finally, a better understanding of how local, regional or national campaigns can work together is needed to inform commissioning decisions, particularly in a UK context.

Acknowledgements

The authors wish to acknowledge the contribution of a number of colleagues during the study. Kathleen Massie, Carol Anne Greenan, Aileen Paton and Graeme Docherty provided administrative and organisational support to the project and we are very grateful for their input. Two University of Stirling postgraduate students assisted with the study and provided very valuable contributions to the research. Naomie Crispin assisted with defining inclusion criteria, review screening, data extraction and quality assessments (for review A) and Joanne Morrison assisted with screening, data extraction, quality assessments and results synthesis (for reviews C and D). We would also like to acknowledge the contribution of members of the study advisory group, in particular George Vekic who provided PPI input throughout.

Advisory group membership

- Professor Annie S Anderson, Professor of Public Health Nutrition, School of Medicine, University of Dundee.
- Professor Kamlesh Khunti, Professor of Primary Care Diabetes and Vascular Medicine, University of Leicester.
- Ms Tara MacLeod, Deputy Director: Strategy, Engagement and Innovation, Public Health England.
- Ms Dona Milne, Deputy Director of Public Health, NHS Lothian.
- Dr Catherine Pritchard, UKCTAS, University of Nottingham.
- Professor Harry Rutter, Director, Halsa Consulting Ltd, Oxford Centre for Healthcare Transformation.
- Mr Paul Thorne, Press Officer, Cancer Research UK.
- Mr George Vekic, Lay Member.

Contributions of authors

Ms Martine Stead (Deputy Director, Institute for Social Marketing, University of Stirling) contributed to the original grant application, was responsible for day-to-day co-ordination of project elements, conducted data appraisal, conducted review and synthesis for *Chapters 2* and *5* and prepared results for publication, drafted *Chapter 7*, devised the overall report structure and contributed to report editing.

Ms Kathryn Angus (Information Specialist, Institute for Social Marketing, University of Stirling) conducted searches, data extraction and appraisal and made a substantial contribution to synthesis and write-up. She contributed to structuring and co-ordinating the final report and managing the referencing for the final report.

Dr Tessa Langley (Associate Professor in Health Economics, Division of Epidemiology and Public Health, University of Nottingham) contributed to the original grant application, supported the management of research staff, conducted data extraction and appraisal, made a substantial contribution to synthesis and write-up, commented on drafts and facilitated stakeholder engagement events.

Dr Srinivasa Vittal Katikireddi (Senior Clinical Research Fellow, Medical Research Council/Chief Scientist Office Social and Public Health Sciences Unit, University of Glasgow) contributed to the original grant application, supported the management of research staff, conducted data extraction and appraisal, made a substantial contribution to synthesis and write-up, commented on drafts and helped facilitate public engagement activities.

[©] Queen's Printer and Controller of HMSO 2019. This work was produced by Stead *et al.* under the terms of a commissioning contract issued by the Secretary of State for Health and Social Care. This issue may be freely reproduced for the purposes of private research and study and extracts (or indeed, the full report) may be included in professional journals provided that suitable acknowledgement is made and the reproduction is not associated with any form of advertising. Applications for commercial reproduction should be addressed to: NIHR Journals Library, National Institute for Health Research, Evaluation, Trials and Studies Coordinating Centre, Alpha House, University of Southampton Science Park, Southampton SO16 7NS, UK.

Ms Kate Hinds (Systematic Reviewer, Institute of Education, University College London) conducted searches, screened records, developed data extraction tools, data extracted and quality appraised the papers and contributed to the methods and the characteristics chapters in the report.

Dr Shona Hilton (Deputy Director, Medical Research Council/Chief Scientist Office Social and Public Health Sciences Unit, University of Glasgow) contributed to the original grant application, conducted data extraction and appraisal and provided a substantial contribution to synthesis and write-up of the report, in particular in *Chapter 7* on characteristics.

Professor Sarah Lewis (Professor of Medical Statistics, Division of Epidemiology and Public Health, University of Nottingham) contributed to study design, data extraction and analysis of subgroup effects on main outcomes, impact of message type and co-supervised the alcohol mass media review.

Professor James Thomas (Professor of Social Research and Policy, Institute of Education, University College London) contributed to the original grant application, co-ordination and team management, the development of tools and methods and writing the final report.

Ms Mhairi Campbell (Systematic Reviewer, Medical Research Council/Chief Scientist Office Social and Public Health Sciences Unit, University of Glasgow) contributed to the literature search of diet studies, conducted quality appraisal, data extraction and synthesis of behavioural outcomes for the review of reviews and prepared the results for publication.

Mr Ben Young (Research Assistant, Division of Epidemiology and Public Health, University of Nottingham) carried out data extraction and quality assessment and conducted the systematic review of alcohol primary studies.

Professor Linda Bauld (Bruce and John Usher Chair in Public Health, Usher Institute, College of Medicine and Veterinary Medicine, University of Edinburgh) was the PI with overall responsibility for the design, co-ordination and delivery of the study and liaising with NIHR. With co-investigators, she conceived, designed and led the original grant application. She made substantial contribution to synthesis and write-up of chapters in the report, commented on drafts and outputs of the study and facilitated stakeholder and public engagement activities.

All authors contributed to the interpretation of findings, writing and editing of the final report and outputs from the study.

- a Definition of a mass media intervention: the intentional use of any media channel(s) of communication by local, regional and national organisations to influence lifestyle behaviour through largely passive or incidental exposure to media campaigns, rather than largely dependent on active help-seeking (adapted from Wakefield *et al.*⁶ and Bala *et al.*²⁷). This excludes, for example, health campaign websites that individuals actively searched for or signed up for.
- b Systematic review must include a specified search strategy from more than one database, an assessment of the quality of studies and some kind of synthesis of the primary studies.

Review (first author and year); risk of bias (ROBIS); relevance to our review of reviews	Review's health topic, aims, coverage and theoretical framework (if used)	Date range of included studies (date range of searches/inclusion criterion)	Number of relevant studies (number of included studies)	Country: UK studies, OECD countries or non-OECD countries	Types of intervention	Types of population/target groups; range of study sample sizes	Synthesis: study design type/subgroup analysis	Types of outcomes: ^a media outcomes, proximal outcomes, intermediate outcomes and distal outcomes
Brinn (2010) ³⁵ Low risk of bias High relevance	Topic: Tobacco use Was mass media sole focus? Yes Aim of review: To determine the strength of the evidence, that mass media interventions to prevent smoking in young people may: 1) reduce smoking uptake among youths (< 25 years), 2) improve smoking attitudes, behaviour and knowledge, 3) improve self-efficacy/self-esteem, 4) improve perceptions about smoking including the choice to follow positive role models	Date range of included studies: 1983–2010 (Date range of searches: 1997–July 2010, date of last search)	Number of studies: Seven relevant studies (of seven included studies)	OECD countries: USA (6), Norway (1)	Reach of included campaigns: Local Community programmes Regional: US states (e.g. California and Massachusetts) Definition of mass media: Channels of communication such as television, radio, newspapers, bill boards, posters, leaflets or booklets intended to reach large numbers of people and which are not dependent on person to person contact Characteristics of the mass media interventions collected by the reviewers: Theoretical framework Basis of programme design Components Start date Duration of the programme Target populations Reach of included campaigns: Local Regional	Target population: Age: < 25 years Range of study sample sizes: 2534–2742; not reported for most	Type of synthesis: Narrative synthesis Type(5) of studies synthesised: RCTs/trials Subgroup analysis: None reported	Media: Awareness Proximal: Intention to smoke Awareness/ knowledge: smoking Attitudes: smoking norms Attitudes: smoking efficacy Intermediate: Behaviour: smoking uptake Distal: None reported

Review (first author and year); risk of bias (ROBIS); relevance to our review of reviews	Review's health topic, aims, coverage and theoretical framework (if used)	Date range of included studies (date range of searches/inclusion criterion)	Number of relevant studies (number of included studies)	Country: UK studies, OECD countries or non-OECD countries	Types of intervention	Types of population/target groups; range of study sample sizes	Synthesis: study design type/subgroup analysis	Types of outcomes: ^a media outcomes, proximal outcomes, intermediate outcomes and distal outcomes	
Brown (2012) ⁵⁶	Topic: Physical activity	Date range of included studies:	Number of studies: 16	Countries: Not reported	Definition of mass media: Stand-alone mass media campaigns:	Target population: No target defined	Type of synthesis: Meta- analysis narrative synthesis	Media: None reported	
High risk of bias	Was mass media sole focus? Yes	1980–2010 relevant studies (of 16 included (Date range of studies) searches:		deliver messages about physical	Range of study	Type(s) of studies	Proximal: None		
High relevance	Aim of review:				sample sizes:	synthesised: RCTs/trials	reported		
	The goal of the systematic review described in this summary was to determine the effectiveness of stand-alone MMCs to increase physical activity at the population level Theoretical Framework	searches: 1980–2011)				activity to large and relatively undifferentiated audiences to increase awareness and/or knowledge about benefits of physical activity, influence attitudes and beliefs about physical activity, and change physical activity behaviors within populations at community, state, or national levels	n = 9755 to n = 74	three controlled trials Cohort/longitudinal study: five cohort studies Observational/correlational: 5 Pre/Post test: three	Intermediate: Behaviour: increased self-report time spent in physical activity Behaviour: increased self-reported activity
							single-group studies using before–after designs ^{19,21,30}	Distal: None	
	The analytic framework applied to this review of standalone mass media interventions is presented in Figure 2. Mass media physical activity campaigns are hypothesized to produce changes in proximal variables, such as heightened awareness and knowledge of the benefits of regular physical activity; and/or more favorable intentions, attitudes, and beliefs about physical activity. These changes can influence				Characteristics of the mass media interventions collected by the reviewers: Components Duration of the programme Dose intensity Coverage/reach of included campaigns		Subgroup analysis: None reported	reported Process: Intervention costs	
	improvements in more-distal outcomes, such as physical activity behaviors, fitness, and, ultimately, reduced morbidity and mortality				Target populations: For updated review Only four studies, ^{32,34,36} two conducted among children and two among adults, met inclusion criteria Cost

Review (first author and year); risk of bias (ROBIS); relevance to our review of reviews	Review's health topic, aims, coverage and theoretical framework (if used)	Date range of included studies (date range of searches/inclusion criterion)	Number of relevant studies (number of included studies)	Country: UK studies, OECD countries or non-OECD countries
Finlay (2005)57	Topic: Physical activity	Date range of included studies:	Number of studies: Eight	UK studies: Three (reported
High risk of bias	Was mass media sole focus? Yes	1998–2002 (part 1), 1980–2002 (part 2)	relevant studies (of eight included	for 1998- studies only)
High relevance	Aim of review:		in initial	
	The 1998–2002 studies (interventions) were reviewed for their success in impacting message recall and behaviour change. The newer studies plus those identified by Kahn et al. (2002) and Marcus et al. (1998), were assessed for the presence of a more sophisticated understanding of the media processes of inception, transmission and reception	(Date range of searches: 1997 (since inclusion in the Marcus <i>et al.</i> 1998 review) to December 2002)	effectiveness analysis plus an additional nine in the critical media analysis, <i>n</i> = 17)	OECD countries: USA (3), UK (3), Australia (1), Canada (1) (reported for 1998 studies only)

Countr ies studies countri non-Ol countri	s, OECD ries or ECD	Types of intervention	Types of population/target groups; range of study sample sizes	Synthesis: study design type/subgroup analysis	Types of outcomes: media outcomes, proximal outcomes, intermediate outcomes and distal outcomes
s for 199 ded only) OECD (countries: a), UK (3), lia (1), ed for	Definition of mass media: An intervention using a component of community-wide mass media (interpersonal communication, workplace or school-based campaigns and small group settings were excluded). Inclusion criterion for 'media' in the title or abstract of the study Characteristics of the mass media interventions collected by the reviewers: Theoretical framework Components Coverage/reach of included campaigns Target populations: see table 1 Reach of included campaigns: Local: e.g. Towns Regional: States in USA e.g. Virginia National: e.g. England	Target population: Not reported Range of study sample sizes: Not reported	Type of synthesis: Narrative synthesis Type(s) of studies synthesised: Pre/Post test Third, the study consisted of a pre-post design assessing a physical activity intervention using a component of community-wide mass media. Studies had to meet this inclusion criteria – no further info given Subgroup analysis: Education Ethnicity	Media: Recall Proximal: Awareness/ knowledge: physical activity Intermediate: Behaviour: increased changes in physical activity Distal: None reported

Review (first author and year); risk of bias (ROBIS); relevance to our review of reviews	Review's health topic, aims, coverage and theoretical framework (if used)	Date range of included studies (date range of searches/inclusion criterion)	Number of relevant studies (number of included studies)	Country: UK studies, OECD countries or non-OECD countries	Types of intervention	Types of population/target groups; range of study sample sizes	Synthesis: study design type/subgroup analysis	Types of outcomes: ^a media outcomes, proximal outcomes, intermediate outcomes and distal outcomes
French (2014) ⁴⁸ Low risk of bias High relevance	Topic: Sexual health Was mass media sole focus? Yes Aim of review: An exploratory review was conducted to assess research examining awareness, acceptability, effects on HIV testing, disclosure and sexual risk, and cost-effectiveness of HIV mass media campaigns targeting MSM	Date range of included studies: 1995–2011 (Date range of searches: between 1990 and May 2011)	Number of studies: 12 relevant studies (of 12 included studies)	UK studies: 7 OECD countries: 7 UK, 4 USA, 1 Canada	Definition of mass media: Mass media campaigns relating to HIV health promotion that targeted MSM were included. Unpaid for media coverage and interactive media health promotion interventions (such as use of internet chat rooms) were excluded. Interventions that only included small media were excluded, but those where mass media were complemented with small media were included Characteristics of the mass media interventions collected by the reviewers: Theoretical framework: Furthermore, only two studies described the theory of change underlying the intervention; one drawing on the Health Belief Model [14] and the other on social marketing concepts [15, 28] Basis of programme design: Formative research was used to inform the development of the campaign concepts, content and materials in five interventions, including: use of focus groups with the target population [14, 15, 18, 23-26, 28], meetings with the alth agencies or community members [16, 23-26], and	Target population: Other: sexual orientation – men having sex with men Range of study sample sizes: 55,270–242	Type of synthesis: Narrative synthesis Pre/Post test Post test Subgroup analysis: Message (campaign)	Media: Awareness Identification Proximal: Behaviour: HIV testing Intermediate: None reported Process outcomes: Intervention costs

Review (first author and year); risk of bias (ROBIS); relevance to our review of	Review's health topic, aims, coverage and theoretical	Date range of included studies (date range of searches/inclusion	Number of relevant studies (number of included	Country: UK studies, OECD countries or non-OECD		Types of population/target groups; range of	Synthesis: study design	Types of outcomes: ^a media outcomes, proximal outcomes, intermediate outcomes and distal
our review of reviews	coverage and theoretical framework (if used)	searches/inclusion criterion)	included studies)	non-OECD countries	Types of intervention	groups; range of study sample sizes	Synthesis: study design type/subgroup analysis	outcomes and distal outcomes

Components

Target populations: Seven targeted all MSM. The remainder targeted specific subgroups of MSM by age or ethnic subgroups, recent unprotected sexual intercourse with men of unknown or discordant HIV status and perceived HIV-negative serostatus. None reported aiming to target MSM according to sexual identity

Cost:

Campaign costs were reported in four studies. Costs ranged from CA\$250,000 for the national campaign in Canada to £9500 for media placement, artists' fees and staff time for the 'Stella Seattle' newspaper comic strip

Intervention

Aim: Most aimed to provide information on HIV prevention strategies and encourage HIV testing. Despite most moving away from basic 'use a condom' messages, few aimed to provide men with information on negotiating safer sex or disclosing their HIV status to a sexual partner

Reach of included campaigns:

Local: Six city-wide

Regional: One US state

National: Four country-wide

Review (first author and year); risk of bias (ROBIS); relevance to our review of reviews	Review's health topic, aims, coverage and theoretical framework (if used)	Date range of included studies (date range of searches/inclusion criterion)	Number of relevant studies (number of included studies)	Country: UK studies, OECD countries or non-OECD countries	Types of intervention	Types of population/target groups; range of study sample sizes	Synthesis: study design type/subgroup analysis	Types of outcomes: ^a media outcomes, proximal outcomes, intermediate outcomes and distal outcomes
Guillaumier (2012) ⁴⁰ Low risk of bias High relevance	Topic: Tobacco use Was mass media sole focus? Yes Aim of review: 1. Systematically review the published evidence of the effectiveness of MMCs (with the primary purpose of encouraging smokers to quit) with smokers from socially disadvantaged groups. 2. Critique methodological quality of the evidence for the effectiveness of mass media campaigns with disadvantaged groups	Date range of included studies 1992–2011 (Date range of searches: Published before March 2012, start of date range not reported)	Number of studies: 17 studies (of 17 included studies)	OECD countries: USA (10), Australia (5), New Zealand (2)	 Definition of mass media: Channels of communication such as television, radio, newspapers, billboards, posters, leaflets or booklets intended to reach large numbers of people, and which are not dependent on person-to-person contact Characteristics of the mass media interventions collected by the reviewers: Start date Duration of the programme Dose intensity Scope Target populations: Ethnic groups (as a marker of disadvantage) Intervention Aim Reach of included campaigns: Local: At least four studies conducted at a community/city level National: At least one study conducted at a national level 	Target population: Age: > 18 years Socioeconomic status: Assess general campaign impacts by measure of equity or disadvantage, or investigate campaigns targeted towards disadvantaged included if they described their sample according to social class, income, education, occupation, ethnic/ racial group and/or SES samples with characteristics associated with high smoking prevalence and socioeconomic disadvantage	Type of synthesis: Narrative synthesis Synthesised: RCTs/trials Cohort/longitudinal study Observational/correlational Pre/Post test Repeated cross-sectional Socioeconomic status	Media: Awareness Credibility Attitudinal/emotional responses Proximal: Intention Motivation Behaviour: information-seeking Intermediate: Behaviour: smoking cessation Distal: None reported
						sample sizes: 198–2714 from five studies ('n' not reported for 12 studies)		

Review (first author and year); risk of bias (ROBIS); relevance to Review's health topic, aims, our review of coverage and theoretical reviews framework (if used)	Date range of included studies (date range of searches/inclusion criterion)	Number of relevant studies (number of included studies)	Country: UK studies, OECD countries or non-OECD countries	Types of intervention	Types of population/target groups; range of study sample sizes	Synthesis: study design type/subgroup analysis	Types of outcomes: ^a media outcomes, proximal outcomes, intermediate outcomes and distal outcomes
Jepson (2006) ⁴³ Topic: Tobacco use Low risk of bias Was mass media sole focus? Yes High relevance Aim of review: To synthesise evidence evaluating the effectiveness of mass media interventions on helping people to quit smoking/tobacco use and/or to prevent relapse. These interventions were considered for both the effectiveness of the channel of communication and also for the effectiveness of message content		Number of studies: 39 relevant studies (of 44 included studies – 5 systematic reviews)	UK studies: 4 OECD countries: USA, New Zealand, Canada, Switzerland, Australia, Wales, Norway, Finland, the Netherlands, UK	Definition of mass media: Channels of communication which are not dependent on person-to-person contact such as: • television • radio • newspapers • bill boards • posters • leaflets or booklets intended to reach large numbers of people • the internet • SMS • podcasts • unpaid publicity through these media – local and national Characteristics of the mass media interventions collected by the reviewers: Scope Target populations Intervention Aim Setting Reach of included campaigns: Local Regional	Target population: Other: People who use tobacco products Range of study sample sizes: Not reported	Type of synthesis: Narrative synthesisType(s) of studies synthesised: RCTs/trialsCohort/longitudinal studyPre/Post testPost testRepeated cross-sectionalOther: Process evaluation; 'observation/ethnography'Subgroup analysis:GenderEducationChannelApproachMessage styleRace/Ethnicity	Media: Awareness Proximal: Behaviour: calls to quitline Intermediate: Behaviour: smoking cessation Distal: Societal change (stigma) Process outcomes: Intervention costs

Review (first author and year); risk of bias (ROBIS); relevance to our review of reviews	Review's health topic, aims, coverage and theoretical framework (if used)	Date range of included studies (date range of searches/inclusion criterion)	Number of relevant studies (number of included studies)	Country: UK studies, OECD countries or non-OECD countries	Types of intervention	Types of population/target groups; range of study sample sizes	Synthesis: study design type/subgroup analysis	Types of outcomes: ^a media outcomes, proximal outcomes, intermediate outcomes and distal outcomes
Leavy (2011) ⁵⁹ High risk of bias	Topic: Physical activity Was mass media sole focus? Yes	Date range of included studies: 2003–10	Number of studies: 18 relevant studies (of 18 included	OECD countries: USA $(n = 8)$, Australia $(n = 3)$, Canada $(n = 3)$,	Definition of mass media: a clear mass media and/or social marketing component that relates specifically to physical activity OR fitness OR exercise;	Target population: Age: Adult	Type of synthesis: Narrative synthesis Type(s) of studies	Media: Awareness Exposure
High relevance	Aim of review: To assess progress and quality of (i) campaign evaluation design and sampling, (ii) use of theory and formative research in campaign development and (iii) evidence of campaign effects including proximal, intermediate and behavioural outcomes Theoretical Framework Campaign impact was classified as: 'proximal' (exposure/awareness), intermediate (knowledge, attitudes, beliefs, saliency and intention or 'initial trial' behaviours) and 'distal' (physical activity behaviour). This typology	(Date range of searches: 2003–10)	studies)	Belgium (n = 1) and New Zealand (n = 1) Non-OECD countries: two were conducted in middle-income countries in South America (Colombia and Brazil)	paid or unpaid media or a combination of both Characteristics of the mass media interventions collected by the reviewers: Theoretical framework Over the 18 campaigns, 'included: theory of reasoned action and planned belief, theory of planned behaviour, McGuire's HOE, stages of change, health belief model, social ecological model and a social marketing framework.' Seven reported a combination. Only half reported formative research Basis of programme design formative evaluations	Range of study sample sizes: 297 – 7217 (Wray and Craig)	synthesised: RCTs/Trials: quasi-experimental Observational/correlational: 'Post-only' cross-sectional designs Pre/Post test: Pre– post– campaign cross-sectional design, repeated cross-sectional Other: Non-experimental, mixed methods design Subgroup analysis: None reported	Proximal: Intention: to be more active Intermediate: Behaviour: increased change in physical activity Distal: None reported Process: Intervention costs
	aligns with the hierarchy of effects (HOE) framework				Components Start date Duration of the programme: Campaign duration ranged from: as short as $8-13$ weeks ($n = 6$); around 6 months ($n = 3$), 12 months ($n = 2$); several phases over 12–24 months ($n = 2$) and greater than 2 years ($n = 5$) Dose intensity Coverage/reach of included campaigns Target populations Cost

Brown (2014) ¹²⁰	Health topic: Tobacco use	Campaign setting: England	Study country: England	Subgroup analyses:	Media outcomes: None reported
Brown (2014) ¹²⁰ OCCS: good	Health topic: Tobacco use: Aim of study To answer three research questions: (I) How effective was Stoptober in promoting quit attempts?; (II) How cost-effective was Stoptober in terms of cost per life year gained?; and (III) What was the public health impact of Stoptober in terms of total life years it is expected to gain? Was mass media sole focus? Yes	 Campaign setting: England Other: Likely UK shared-media channels survey only measured additional quitting in England, and although the campaign only targeted England directly, there was almost certainly a positive related effect of the campaign on quitting in other countries of the United Kingdom Characteristics: Campaign aim Stoptober encouraged smokers to join a mass quit attempt on October 1st 2012 and stay smoke-free throughout October with a variety of support including digital to help them achieve success Theoretical framework: 3 psychological principles: SOCIAL CONTAGION THEORY that one can use messaging to amplify a campaign the use of a SMART goal PRIME THEORY is a comprehensive theory of motivation that argues behaviour is determined on a moment-to-moment basis by a wide variety of motivational inputs Basis of programme design The stimulus for the campaign was twofold: first was the observation that 'No Smoking Day' which takes place every year in March throughout England Secondly, it was noticed 	<pre>Study country: England Sample size: n = 31,566 adult (≥ 16 years) past-year smokers Date of data collection: 2007–12 Study design: Repeated Cross Sectional examining the percentage of smokers reporting a past-month quit attempt in a series of monthly cross-sectional household surveys of representative samples of the population of adults in England between 2007 and 2012 Data collection method Survey: a face-to-face computer-assisted survey with a trained interviewer</pre>	Subgroup analyses: Age Gender Socioeconomic status Time	Media outcomes: None reported Proximal outcomes: None reported Intermediate outcomes: Behavioural: attempt to change behaviour Distal outcomes: Improvement in population health status Process outcomes: Cost-effectiveness data

itudy (first author and rear) quality ating	Study topic and aim	Mass media intervention	Sample and study design	Subgroup analyses	Types of outcomes: media outcomes, proximal outcome intermediate outcomes, dista outcomes, process outcomes
		Duration of the programme: month of October			
		Scope: National campaign in England			
		Target populations: All smokers			
		Cost			
		The known costs of Stoptober provided by the Department of Health were £5.8 million media advertising £3,380,000; public relations £70,000; local and regional activation of the campaign among participating organisations £500,000; fees for development and fulfilment of all creatives £1,820,000; follow on communications £30,000			
		Components:			
		Channels			
		The campaign was broadcast through a combination of traditional and new mass media including TV, press, radio and online adverts, public relations messaging, and Facebook and Twitter activity			
		Channel Interactivity			
		a peer support via Facebook, a motivational text-messaging programme and an app that aimed to provide ongoing encouragement and self-monitoring tools			
		Messages			
		 (i) frequent positive messaging encouraging smokers to stop (ii) providing an opportunity to do so at the same time as others 			
		achieving this goal would be at least five times more likely to become permanent ex-smokers having recovered from the worst of the cravings and withdrawal symptoms			

Study (first author and year) quality rating	Study topic and aim	Mass media intervention	Sample and study design	Subgroup analyses	Types of outcomes: media outcomes, proximal outcomes, intermediate outcomes, distal outcomes, process outcomes
		Targeting strategies included Local and regional activation of the campaign among participating organisations including the national Stop Smoking Services Branding: Not described as a brand, but: The campaign was named 'Stoptober', as a combination of Stop and October, and was designed to build wide engagement with the event from association with other positive, popular national events that have successfully used similar monikers (e.g. 'Movember') and to encourage easy dissemination Other support materials Support tools to help smokers achieve a smoke-free month included a postal quitting pack and range of digital tools including an accompanying website that offered brief advice on smoking cessation, motivational text-messaqing			
Brown (2016) ¹³⁶	Health topic: Tobacco use	and an app to provide ongoing support and self-monitoring tools Campaign setting: UK (no further breakdown)	Study country: UK (no further breakdown)		Media outcomes:

Did not examine one or more of the relevant health behaviours

Intervention did not meet the mass media definition^a

Linked to a previously excluded study

Intervention did not meet the mass media definition^a

Excluded on outcomes data

Did not examine one or more of the relevant health behaviours

Intervention did not meet the mass media definition^a

a Eligible: a mass media campaign broadcast using television, radio, cinema, online broadcasting, newspapers and magazines, leaflets/booklets, direct mail, outdoor advertising, text messaging, e-mail and digital media, including websites and banner advertisements. Ineligible: (a) interventions involving person-to-person contact, requiring active engagement before receipt of the message (e.g. alcohol screening questions) rather than passive message exposure, or online treatment or self-help programmes; (b) studies in which a baseline measure is used to tailor a subsequent mass media message; (c) studies testing campaign messages, rather than assessing implemented campaigns intended to reach large numbers of people – exclude studies of messages taken from an implemented campaign but delivered and evaluated outside that campaign (e.g. in laboratory conditions); (d) studies of multicomponent interventions if they do not assess the specific effects of a mass media component; (e) studies assessing the impact of advertisement bans; (f) studies of social norms campaigns unless it is evident from the information available that a mass media channel was used – if an intervention is described only as a social norms or social marketing campaign and there is no information indicating the use of mass media channels then it will be ineligible for inclusion; (g) studies of obligatory health warnings (e.g. on-pack health warnings; point-of-sale health warnings), evaluating policies rather campaigns.

Using the mass media for public health: what's the evidence?

Thursday 28th September 2017, 12-4pm Iris Murdoch Building, University of Stirling FREE

Presentations include:

Please RSVP to Kate Massie.

- Developing and using logic models Professor James Thomas, EPPI Centre, University College London
- Outcomes and costs: mass media campaigns Dr Vittal Katikireddi, University of Glasgow, and Dr Tessa Langley, University of Nottingham
- Public health mass media campaigns on alcohol Professor Sarah Lewis and Ben Young, University of Nottingham
- What makes a successful mass media campaign? Focus on characteristics Dr Shona Hilton, University of Glasgow
- Gaps and opportunities: what our reviews tell us about future research on mass media campaigns for public health Martine Stead, University of Stirling
- The future for mass media campaigns Prof Linda Bauld. University of Stirling

if you would like to attend The study was funded by the National Institute of Health Research Public Health Research Programme, Project Number 13/163/17

Appendix 10 Agenda for 'Using the mass media for public health: what's the evidence?' stakeholder event, September 2017

Mass media for public health messages: end-of-study event

Date: 28 September 2017.

Venue: Iris Murdoch Building, University of Stirling.

Time: 12–4 p.m.

Agenda

Chairperson: Professor Linda Bauld, Institute for Social Marketing, University of Stirling.

12.00–12.30 Sandwich lunch on arrival.

12.30–12.45 Background to the study and examples of campaigns – Professor Linda Bauld, University of Stirling.

12.45–13.00 Developing and using logic models – Professor James Thomas, EPPI Centre, University College London.

13.00–13.20 Outcomes and costs: mass media campaigns – Dr Vittal Katikireddi, University of Glasgow, and Dr Tessa Langley, University of Nottingham.

13.20–13.40 Public health mass media campaigns on alcohol – Professor Sarah Lewis and Ben Young, University of Nottingham.

13.40-14.15 Discussion in small groups: what does the evidence tell us about the effective use of mass media?

14.15–14.35 Coffee.

14.35–15.00 What makes a successful mass media campaign? Focus on characteristics – Dr Shona Hilton, University of Glasgow.

15.00–15.15 Gaps and opportunities: what our reviews tell us about future research on mass media campaigns for public health – Martine Stead, University of Stirling.

15.15–15.45 Discussion in small groups: priorities for future monitoring, evaluation and research.

15.45–16.00 Summing up – Professor Linda Bauld, University of Stirling.

The study is funded by the National Institute for Health Research, PHR project 13/163/17.
