THE FADDEEV APFFOAこH IC HIGH ENEIGY AIOMIO COLLISIONS AND THE SIGNIFICANO OT CO RESPONDFNCE IDENNITIES.
by

> NEJL YUTTON, B.S̃c.

Thesis submitter to the University of Stirling for the degres of Doctor of Philosophy.

Physics Departmert University of Stir2in?

STIRLING,
November, 1973.

The Faddeev equations enable onc to express the scattering amplitude for a three-body process inveracting via binary potentials in terms of the two-body off-shell Coulomb $T$ matrices. In the first order iterate the equations reduce to a sum of two terms. A form of the two-body off-shell Coulomb $T$ matrix is presented which can be expressed partially as a sum over the classical trajectories of the scattering particles. It is shown that in the limit of high energies and non-zero scattering angles an on-shell correspondence identity exists for this $T$ matrix, so that only the classical path term contributes to the scattering amplitude.

The classical path approximation is applied to elastic and inelastic coliisions of electrons on hydrogen atoms. For elastic collisions the first order Faddeev approximation predicts differential cross sections considerably larger than those predicted by the first Born approximation at energies where the Born approximation is expected to be good. At angles of scattering above $30^{\circ}$ our results are identical to those calculated using a different exact form of the Coulomb $T$ matrix (Chen and Sinfailam, 1972). In the Faddeev
approximation the differential cross section diverges at small angles of scattering. The angular and energy distributions of the differential cross section for inelastic collisions are close to the predictions of the Coulomb projected Born approximation (Geltman and Hidalgo, 1971), though the latter approximation predicts much smaller cross sections. Singularities in the on-shell Coulomb $T$ matrix associated with the long range nature of the Coulomb potential are responsible for both the zero angle divergence and the overestimation of the differential cross section in the Faddeev approximation.

In conclusion we comment on the importance of recent calculations of the second-order iterate of the Faddeev equations for electron-hydrogen scattering (Chen et.al., 1973) where it is shown that the differential cross section for elastic scattering approaches the Born result. This demonstrates that cancellation occurs between the singularities in the first-order and second-order terms of the Faddeev equations.

## ACKMCOLEUSEMENCS

This analysis of the two-body off-shell Coulomb $T$ matrix was initiated by Dr. M.J. Roberts. I should like to thank him for the sound supervision and advice which was always made readily available during this research project. I should like to thank my colleagues in the Physics Department at Stirling, many of whom at ore time or another helped my understanding of atomic physics. In particular Frofessor I.C. Percival aid Dr. D. Banks made inspiring comments on my research topic, and the latter gave invaluable assistance with numerical calculations. I am grateful to Professor J.C.Y. Chen of the University of California for enlightening conversations and for providing me with copies of his work in advance of publication.

During the period of research I was financially aided by the Science Research Council to which I am grateful.

## CHAPTER 1

## PRELIMINARIES

### 1.1 Introduction

The theoretical study of electron atom collisions has attracted physicists for over half a century (for a detailed review see Mott and Massey). In many instances the studies have been limited to one of the simplest atomic collision processes, namely the scattering of electrons by atomic hydrogen. This process is a three-hojy collision involving a system which initially consists of an incilent electron and a bound electron and proton pair. An exact solution of the three-body problem has long eluded physicists, however recent work by Faddeev (1961, 1963, 1965, 1970) led to a more rigorous analysis of the problem than hitherto. Chen and Joachain (1971) have shown that Faddeev's analysis for three bodies is equivalent to a symmetric version of the Watson multiple-scattering theory (Goldberger and Watson, p.749).

Earlier calculations on the collision process, both quantal and classical, had met with limited success. An extreme paucity of absolu'te experimental measurements of the differential and total cross sections for electron hydrogen collisions had made interpretation of theoretical results difficult. It
is not the purpose of this thesis to formulate a classical description of the scatterirg process, though correspondence identities between quantum mechanical results obtained and classical concepts will be emphasised, so we refer the reader to a review by Burgess and Percival (1963) for developments in classical scatterire theory.

In quantum mechanical calculaさions the approximation used depends mainly on the energy at which the collision takes place. For low energy collisions much scattering data has been obtained from applications of the close coupling and related methods (see for instance, Burke and Seaton, 1971). We shall be more interested in the scattering of electrons by hydrogen atoms at high energies, where the most common approximation used is that of Born (1925). This method is briefly described in operator notation below.

1. 2 Sattering cross sections and the Born approximation

The quantities of most interest to us in collision theory are cross sections. The differential cross section, do/du , is defined as the intensity of scattered particles per unit solid angle per unit flux, measured at large distances from the scattering interaction itself. The differential cross section for the scattering of a particle by a bound pair interacting via a potential $V$ is (Messiah, ps.906, 835).

$$
\begin{equation*}
\left.\frac{d \sigma}{d \Omega}=\frac{m^{2}}{4 \pi^{2} \hbar^{4}}\left|\left\langle\phi_{F}\right| V\right| \psi_{i}^{(+)}\right\rangle\left.\right|^{2} \tag{1.1}
\end{equation*}
$$

where $\mu$ is the mass of the incident particle reduced relative to the centre of mass of the bound pair. Here, and throughout this thesis, $\phi_{f}$ represents a final state of the system in the absence of interaction, whereas $\psi_{( }^{(+)}$is the initial full solution of the Schrodinger equation determined by the boundary conditions relajed to the scattering of the incident particle. The factor $\left(\mu^{2} / 4 \pi^{2} \hbar^{4}\right)$ is dependent on the normalisajion chosen for the initial and final states. Expression (1.1) is exact; the Born approximation expresses $\psi_{i}^{(+)}$, and thus
$\frac{d o}{d \sqrt{R}}$, in increasing powers of the potential $V$.

The first Born approximation is obtained by replacing
$\psi_{i}{ }^{(+)}$with the unperturbed state $\phi_{i}$. Essentially one says that the potential $V$ is so weak that the system is unperturbed by the passage of the incident particle, an approximation which is known to be good for high energy incident particles (Messiah, p. \$13). Successive approximations in the Born expansion are obtained by using the following expansion for $\left|\psi_{i}^{(+)}\right\rangle$,

$$
\begin{equation*}
\left|\psi_{i}^{(+)}\right\rangle=\left(1+\sum_{N=1}^{\sum}\left[G_{c}^{(+)}(E) v\right]^{N}\right)\left|\phi_{i}\right\rangle \tag{1.2}
\end{equation*}
$$

$G_{0}^{(+1}(E)$ is the free-wave Green function with outgoing wave asymptotic behaviour for three non-interacting
pariicles and total energy $E$. Ne will find it useful to express the second term in Equation (1.2) in terms of the outroing scattered wave Green function $G^{(1)}(E)$ (N.essiah, p.82引)

$$
\begin{equation*}
\sum_{N=1}^{\infty}\left[G_{0}^{(t)}(E) V\right]^{N}=G^{(+)}(E) V \tag{1.3}
\end{equation*}
$$

The ability of the Born expansion method to give a value of $d \sigma / d \Omega$ close to the exact value, depends on the convergence of the expansion (1.2). Nhilst the Born series has been show: to converge quickly at high energies for the potential scattering of a particle (Zemaci and Klein, 1953), the convergence properties for complex collisions are not well understood. For three-body collisions, Newton (p.557) has shown that $\delta$-functions oscur in the analysis which make t-e integral kernels for the Born expansion badly behaved. In particular for the case of rearrangement collisions Aaron et.al. (1961) have suggested that the Born series is divergent, though we note that this claim has been refuted by Dettmann and Leibfried (1968). This scepticism about the convergence properties of the Born expansion led to a new formulation of Equation (1.1) in terms of the Toperator, and to the more detailed analys is of Faddeev.

### 1.3 The T Operator and than Fafdecy Equations

The $T$ operator is defined in matrix representation by its elements

$$
T_{i f}=\left\langle\phi_{F}\right| T\left|\phi_{i}\right\rangle=\left\langle\phi_{F}\right| V\left|\psi_{i}^{(+)}\right\rangle
$$

The first Born approximation to the $T$ matrix is thus

$$
\begin{equation*}
T_{i f}^{B}=\left\langle\phi_{f}\right| V\left|\phi_{i}\right\rangle \tag{1.5}
\end{equation*}
$$

We can define the differential cross section directly in terms of the $T$ matrix from Equation (1.1)

$$
\begin{equation*}
\frac{d \sigma}{d \Omega}=\frac{\mu^{2}}{4 \pi^{2} \hbar^{4}}\left|T_{i f}\right|^{2} \tag{1.6}
\end{equation*}
$$

In this formalism the matrix elements are taken between free state wave functions which can be written down exactly for the problems we are to consider.

Using Equations (1.2) - (1.4) we can obtain, using simple operator algebra, the following formal expressions for the three-body $T$ operator

$$
\begin{equation*}
T(E)=V+V G^{(+)}(E) V \tag{1.7a}
\end{equation*}
$$

$$
\begin{equation*}
\text { and } T(E)=V+V G_{0}^{(+)}(E) T(E) \tag{1.7b}
\end{equation*}
$$

For three particles interacting only via two-body potentials, the interaction potential is given by

$$
\begin{equation*}
V=\sum_{i=1}^{3} V_{i} \tag{1.8}
\end{equation*}
$$

where $V_{i}$ represents the two-bndy interaction between particles $j$ and $k$, We can then introduce the two-body $T$ operascrs, $T_{i}(i=1,2,3)$, which are defined in terms of the two-body free wave Green function $G_{0}^{(t)}(E)$,

$$
\begin{equation*}
T_{i}(E)=V_{i}+V_{i} G_{0}^{\left({ }^{(1)}\right.}(E) T_{i}(E) \tag{1.9}
\end{equation*}
$$

$T_{i}(E)$ represents the two-body $T$ matrix for the interaction between particles $j$ and $k$ with particle $i$ as a spectator. We evaluate the matrix elements of
$T_{i}(E)$ between momentum staves; that is, $\left.\left.\langle f| T_{i}(E)\right|_{f}{ }^{\prime}\right\rangle$. In this case the energies associated with the states $|f\rangle$ and $|f '\rangle$ are not equal to $E$, and the matrix element is known as the off-shell $T$ matrix. The differential cross section is related to the threebody $T$ matrix which is on-shell, i.e. the energies associated with $\phi_{f}$ and $\phi_{i}$ both equal $E$. This is related in turn to the two-body off-shell $T$ matrices.

Consider the three-body direct scattering process,

$$
\begin{equation*}
1+(2,3) \longrightarrow 1+(2,3) \tag{1.10}
\end{equation*}
$$

The three-body $T$ operator for this process, elastic or inelastic, is $T_{D}$ and this, can be expressed in terms of the two-body $T$ operators (Chen and Joachain, 1971),

$$
\cdot T_{D}=\tau_{21}+\tau_{31}
$$

$$
\begin{equation*}
\tau_{k 1}=T_{k}\left(\delta_{k 2}+\delta_{k 3}\right)+\sum_{j \neq k} T_{k} G_{0} \tau_{j^{\prime}} \tag{1.11}
\end{equation*}
$$

These are the Fadlecv equations for process (1.10) which are written more explicitly to third order below

$$
\begin{aligned}
T_{0}= & T_{2}+T_{3}+T_{2} G_{0} T_{3}+T_{3} G_{0} T_{2}+T_{2} G_{0} T_{1} G_{0} T_{2} \\
& +T_{2} G_{0} T_{1} G_{0} T_{3}+T_{2} G_{0} T_{3} G_{0} T_{2}+T_{3} G_{0} T_{1} G_{0} T_{2} \\
& +T_{3} G_{0} T_{1} G_{0} T_{3}+T_{3} G_{0} T_{2} G_{0} T_{3}+\cdots \cdots
\end{aligned}
$$

The first order Faddeev approximation is given by retaining only the first two terms of Equation (1.12). These terms are purely two-body ard no three-body couplings are included in this approximation. Using Equations $(1.4),(1.6)$ and (1.12) we can write the differential cross section in terms of the first order iterate of the Faddeev equations,

$$
\begin{equation*}
\left.\frac{d \sigma}{d v}=\frac{\mu^{2}}{4 \pi^{2} \hbar^{4}}\left|\left\langle\phi_{F}\right| T_{2}+T_{3}\right| \phi_{i}\right\rangle\left.\right|^{2} \tag{1.13}
\end{equation*}
$$

The convergence of the Faddeev expansion has been studied rigorously (Faddeev, 1965). It has been shown diagramatically (Chen and Joashain, 1971) that the Faddeev expansion should have better convergence properties than the Born series. Once the two-body $T$ matrices for each pair interaction are krown, then using successive iterations of the Faddeev equations one can in principle obtain a solution of the scattering problem.

An extensive review of the Coulomi problem has recently been piven by Cher and Chen, (1972), and they have shown that knowlefee of the two-body off-shell Coulomb $T$ matrix leads in principle to a complete solution. The properties and a particular representation of the two-body off-shell Coulomb Tratrix will be discussed in Chapter 2. Norcliffe et.al. (19EN have obtained corresponderce identities betweer. quaritum mechanics and classical mechanics for the two-body interaction in momemtum space. The Fadreev equations can be used to extend the investigation of these identities to three body processes, where classical calculations using Monte Carlo methods (Burgess and Percival, 1968) have recently been made with considerable success. Using the identities of Norcliffe et.al., we can obtain an expression for the Coulomb $T$ matrix which can be expressed partially in terms of the classical trajectories of the colliding particles. We shall compare this expression with representations derived by Chen and Chen (1972) and other workers.

The application of the Faddeev equations to atomic collision processes using Chen's form of the two-body off-shell Coulomb $T$ matrix has been extensive in the past five years (Chen, 1971). For low energy problems, using a separable expansion form of the Coulomb $T$ matrix due to Ball et.al. (1968), calculations of the three-body bound states for atomic systems have been carried out successfully.

At energies above the ionization threshold the analytic form of the Coulomb ${ }^{T}$ matrix is less well understood. However calculaiions have been carried out for many atomic scattering processes and interestine comparisons with the Born and other approximations have been obtained.

In Crapters 3 and 4, we shall use the classical path form of the Coulomb $T$ matrix, referred to earlier, in the Faddeev equations and investigate the elastic and inelastic direct scattering of electrons on hydrozen atoms. We shall compare our results with experimental and other theoretical predictions, and concluje by assessing the use of the classical path form of the Coulomb $T$ matrix and the Faddeev equations in predicting cross sections for atomic collision processes.

This thesis is based on a series puolished on the off-shell Coulomb $T$ matrix by Roberts (1970), Hutton and Roberts (1972) and Hutton (1972).

## CHAPTER 2

### 2.1 Introduction

In this chapter we consider the two-body Coulomb interaction between particles of mass $m_{1}$ and $m_{2}$ and asymptotic momenta $\underline{k}_{1}$ and $\underline{k}_{2}$. It is well known that a complete solution of this problem can in principle be obtained through knowledge of the Coulomb Green function. After separating out the total two-body momentum we car express this function as a matrix element in relative momentum representation, $\left.\left.\langle p| G^{(+)}(E)\right|_{p^{\prime}}\right\rangle$, where $E$ is the total centre of mass energy. The relative momenta $f$ and $f^{\prime}$, and the reduced mass in the two-body system are given by (Chen and Cher., 1972)

$$
\begin{align*}
& f=\frac{m_{2} k_{1}-m_{1} \underline{k}_{2}}{m_{1}+m_{2}} \\
& \mu_{12}=\frac{m_{1} m_{2}}{m_{1}+m_{2}} \tag{2.1}
\end{align*}
$$

and the two-particle kinetic energy operator is

$$
\begin{equation*}
H_{0}=\frac{p^{2}}{2 \mu_{12}} \tag{2.2}
\end{equation*}
$$

The two-body off-shell Coulomb $T$ matrix is related
to the Green function by (Lippman and Schwinger, 1950),

$$
\begin{aligned}
\langle o| G^{(+)}(E)\left|p_{p}^{\prime}\right\rangle & \left.=\left.\langle p| G_{0}^{(+)}(E)\right|_{p^{\prime}}\right\rangle \\
& \left.\left.+\left.\left\langle{ }_{p}\right| G_{0}^{(+)}(E)\left|p^{\prime}\right\rangle\left\langle{ }_{p}\right| T(E)\right|_{p^{\prime}}\right\rangle\left.\langle p| G_{0}^{(+)}(E)\right|_{f^{\prime}}\right\rangle
\end{aligned}
$$

Here $\langle p| G^{(+)}(E)\left|f^{\prime}\right\rangle$ is the full outroing wave Green function, and $\left.\left.\left\langle_{p}\right| G_{0}{ }^{(1)}(E)\right|_{f^{\prime}}\right\rangle$ is the Green function in absence of any interaction, both been given in momentum representation. Thus, having obtained an explicit form for the Coulomb Green function one should be able to deduce the scattering matrix
$\left.\left.\left\langle_{f}\right| T(E)\right|_{f} ^{\prime}\right\rangle$, and on substituting the latter in the Faddeev equations solve the scattering problem.
2.2 The Coulomb Green function

In momentum representation the Coulomb Green function for the relative motion of two interacting particles of charge $Z_{1}$ and $Z_{2}$ satisfies the integral equation (Perelemov and Popov, 1956),
$\left(\frac{\rho^{2}}{2 \mu_{12}}-E\right)\langle p| G(E)\left|p^{\prime}\right\rangle+\frac{Z_{1} Z_{2} e^{2}}{2 \pi^{2} \hbar} \int \frac{\left.\left.\left\langle q^{\prime \prime}\right| G(E)\right|_{p^{\prime}}\right\rangle}{\left|p-f^{\prime \prime}\right|^{2}} d_{p^{\prime \prime}}$

$$
\begin{equation*}
=-\delta\left(p-f^{\prime}\right) \tag{2.4}
\end{equation*}
$$

Perelemov and Popov, and also Schwinger (1964) have used the symmetric transformation (Fork, 1935) to bring this equation into a form invariant with respect to the symmetry group of the hydrogen atom for negative energies, the $O(4)$ group, and for positive energies, the $O(3,1)$ group. They introduce the four vectors $\varepsilon_{\mu}(\mu=0,1,2,3)$ defined as, $(i=0,1,2,3)$,

$$
\begin{array}{rlrl}
\varepsilon_{i}= & 2 p_{E} p_{i} /\left(p^{2}+p_{e}^{2}\right) & & E<0 \\
& 2 p_{E} p_{i} /\left(p^{2}-p_{E}^{2}\right) & E>0(2.5 a) \\
\varepsilon_{0}= & \left(p_{E}^{2}-p^{2}\right) /\left(p_{E}^{2}+p^{2}\right) & E<O \\
& =\left(p_{E}^{2}+p^{2}\right) /\left(p^{2}-p_{E}^{2}\right) & E>0(2.5 b)
\end{array}
$$

where $P_{E}=\left.2 \mu_{12} I E\right|^{1 / 2}$. A point with these coordinates lies on a four-dimensioral hypersphere which is topographically a hypersphere for $E<0$ but for positive energies is a hyperboloid of two sheets. The Coulomb Green function in terms of these coordinates is,

$$
G\left(\varepsilon, \varepsilon^{\prime}\right)=\frac{-1}{16 \mu_{12} p_{E}^{3}}\left(p^{2} \pm p_{E^{2}}\right)^{2}\langle q| G^{(H)}(E)\left|f^{\prime}\right\rangle\left(p^{\prime 2} \pm p_{E}^{2}\right)^{2}(2.5)
$$

The upper signs here (and in Equation (2.7)) refer to the $E<O$ case, the lower signs to the $E>O$ case. Equation (2.4) becomes in $\varepsilon$-space
$G\left(\varepsilon, \varepsilon^{\prime}\right) \pm \frac{3}{2 \pi^{2}} \int \frac{d^{3} \varepsilon^{\prime \prime}}{\varepsilon_{0}^{\prime \prime}} \frac{G\left(\varepsilon^{\prime \prime}, \varepsilon^{\prime}\right)}{\left(\varepsilon-\varepsilon^{\prime \prime}\right)^{2}}=\delta\left(\varepsilon-\varepsilon^{\prime}\right) \underset{\substack{ \\z_{1}, 2, e^{2} \mu_{1}}}{(2,7)}$ Where 3 is the Coulomb interaction parameter, $\beta=\frac{z_{12} 2_{1} e^{2} \mu_{12}}{\hbar} \rho_{\varepsilon}$ (2.8). For the $E<0$ case Schwinger (1964) has obtained an expression for $G\left(\varepsilon, \varepsilon^{\prime}\right)$ in terms of the basis functions $Y_{\text {mem }}(\mathcal{E})$ of the irreducible representations of the $O(4)$ group,

$$
\begin{equation*}
G\left(\varepsilon, \varepsilon^{\prime}\right)=\sum_{n=1}^{\infty} \sum_{\varepsilon=0}^{n-1} \sum_{n=e}^{+1} \frac{Y_{n e m}(\varepsilon) Y_{n=m}^{*}\left(\varepsilon^{\prime}\right)}{1+N_{3}} \tag{2.9}
\end{equation*}
$$

The $Y_{\text {mem }}(\varepsilon)$ are the four-dimensional spherical harmonics which have been studied in detail by Pock and Bander and Itzykson (1966). They are defined on the surface of a four dimensional unit hypersphere and we can define the angle $\mathcal{X}_{\text {, }}$ between the vectors $\varepsilon$ and $\varepsilon^{\prime}$ on the hypersphere by the relation $\left|\varepsilon-\varepsilon^{\prime}\right|=2 \sin \left(X_{/ 2}\right)$. Making use of a summation rule for the functions $Y_{\text {hem }}(\varepsilon)$, Perclemov and Popov were able to formulate an expression for $G\left(\varepsilon, \varepsilon^{\prime}\right)$ in terms of known analytic functions,

$$
\begin{aligned}
& G\left(\varepsilon, \varepsilon^{\prime}\right)=\delta\left(\varepsilon-\varepsilon^{\prime}\right)-\frac{n}{2 \pi^{2}\left(\varepsilon-\varepsilon^{\prime}\right)^{2}} \\
&+\frac{3^{2}}{4 \pi^{2} i \sin x}\left[\Phi\left(e^{i \psi}, 3\right)-\Phi\left(e^{-i k}, \beta\right)\right]
\end{aligned}
$$

where $\Phi(z, \beta)$ is defined by

$$
\Phi(z, B)=\sum_{n=0}^{\infty} \frac{z^{n}}{n+3} \quad, \quad|z|<1 \quad \text { (2.11) }
$$

$\Phi(z, 3)$ can be analytically continued into the whole complex $z$-plane apart from the real axis cut. $1<z<\infty$.

Pertemov and Popov extended their analysis by presenting a prescription for analytic continuation of the Green function $G\left(\varepsilon, \varepsilon^{\prime}\right)$ into the whole complex plane apart from the positive real axis branch cut. For positive energies two different Green functions $G^{( \pm)}\left(\varepsilon, \varepsilon^{\prime}\right)$ are defined on the upper and lower edge of the $0<E<\infty$ cut (Newton, p.178). In position representation these correspond to the outgoing and incoming wave Green functions, and it is the outgoing or scattered wave $G$ cen function $G^{(t)}$ which appears in Equation (2.3) for the scattering matrix. Introducing the sign function

$$
\begin{aligned}
& +1 \text { on the upper edge of the cut }\left(E=E_{0}+i \delta\right) \\
& (2.12) \\
& -1 \text { on the lower edge of the cut }\left(E=E_{0}-i s\right)
\end{aligned}
$$

Perlemov and Popov obtain the following representation for $G\left(\varepsilon, \varepsilon^{\prime}\right)$,

$$
G\left(\varepsilon, \varepsilon^{\prime}\right)=\delta\left(\varepsilon-\varepsilon^{\prime}\right) \mp \frac{\beta}{2 \pi^{2}\left(\varepsilon-\varepsilon^{\prime}\right)^{2}}+\frac{3^{2}}{2 \pi^{2}} F\left(\varepsilon, \varepsilon^{\prime \prime}\right) \quad \text { (2.13) }
$$

where the sign + agrees with the sion of $E$, and the function $F\left(E, E^{\prime}\right)$ has the following integral representations in the different regions of energy and momentum space,

$$
\begin{aligned}
& F\left(\varepsilon, \varepsilon^{\prime}\right)=\frac{3}{\sin x} \int_{0}^{\infty} \frac{\sinh (\pi-x) k}{\sinh \pi k} \frac{d k}{k^{2}+3^{2}}, \quad E<0(2.14 a) \\
& F\left(\varepsilon, \varepsilon^{\prime}\right)=\frac{1}{\sinh \omega} \int_{0}^{\infty} \frac{k-3 \operatorname{coth} \pi k}{k^{2}-3^{2}+i \sigma \delta} \sin k \omega d k, \quad E>O(2.14 b) \\
& F\left(\varepsilon, \varepsilon^{\prime}\right)=\frac{-1}{\sin h \omega} \int_{0}^{\infty} \frac{k+3 \operatorname{coth} \pi k}{k^{2}-3^{2}+i \sigma \delta} \sin k \omega d k, \quad \begin{array}{l}
\quad E>0 \\
P, \rho^{\prime}<P E
\end{array}(2.14 c)
\end{aligned}
$$

or $P\left\langle P E, P^{\prime}>P E\right.$

For $E>0 \quad \omega$ is a hyperbolic angle between the vectors $\mathcal{E}$ and $\boldsymbol{\varepsilon}^{\prime}$, (which may be on different sheets of the hyperboloid), and is defined in the different regions of momentum space by,

$$
\left(\varepsilon-\varepsilon^{\prime}\right)^{2}=\begin{array}{r}
-4 \sinh ^{2}\left(\omega_{2}\right) \text { for } p_{1} p^{\prime}>p_{E} \text { or } p_{1} p^{\prime}<p_{E} \\
4 \cosh ^{2}(\omega / 2) \text { for } p^{\prime} p_{E}, p^{\prime}<p_{E} \text { or } p^{\prime}\left\langle p_{E}, p^{\prime}>p_{E}\right. \tag{2.15}
\end{array}
$$

Roberts (1970) has calculated the positive energy Coulomb Green function directly in the $0(3,1)$ representation (Bander and Itzykson, 1956) and transformed to momentum representation. Earlier work by Norcliffe et.al. (1969) had shown that the spectral operator $I_{z}=\lim _{\delta \rightarrow 0}(2 \pi i)^{-1}\left(G^{(-)}-G^{(+)}\right)$for the Coulomb interaction could be expressed as a sum over classical paths, and this motivated Roberts to examine the dependence of the Green function on classical paths.

Roberts gives the following expression for the Green function in momentum representation,

$$
\begin{equation*}
\left.\left.\langle p| G(E)\right|_{p^{\prime}}\right\rangle=G_{0}+G_{1}+\frac{16 \mu_{12} p_{E}^{3} \mathcal{g}^{( \pm)}}{\left(\rho^{2}-p_{E^{2}}^{2}\right)^{2}\left(p^{12}-p_{E}^{2}\right)^{2}} \tag{2.16}
\end{equation*}
$$

where $G_{0}$ and $G_{1}$ are the well known zeroth and first order perturbation terms. $\mathscr{g}^{(t)}$ has the following different forms in ( $p-p^{\prime}$ ) -space

$g^{(t)}=\frac{-v^{3}}{4 \pi^{2} \sinh \omega} \sum_{n=-\infty}^{\infty} \frac{(-1)^{n} \exp p(-\operatorname{nin}(\omega)}{n^{2}+\nu^{2}}+\frac{\left.\nu^{2} \exp (-n \nu)\right) \exp (\neq i v \omega)}{2 \pi(1-\exp (-2 \nu \nu)) \sinh (2.17 b)}$

$$
p^{\prime}>p_{e}, p^{\prime}\left\langle p_{E} \text { or } p^{\prime}\left\langle p_{E}, p^{\prime}\right\rangle p_{E}\right.
$$

$$
G^{(t)}=\frac{v^{3}}{4 \pi^{2} \sinh \omega} \sum_{n=-\infty}^{\infty} \frac{\exp (-\ln \mid \omega)}{2^{2}+\nu^{2}}-\frac{\nu^{2} \exp (-2 \pi \nu) \exp (\operatorname{tiv} \omega)}{2 \pi(1-\exp (-2 \nu \nu)) \sinh \omega)}(2.17 c)
$$

$$
p_{1} \rho^{\prime}<p_{E}
$$

where the hyperbolic angle is defined by
and $\downarrow$ is defined slightly differently from the 3 of Perelemov and Popov by

$$
\begin{equation*}
\nu=\frac{\left|z_{1} z_{2}\right| e^{2} \mu_{12}}{\hbar p_{E}} \tag{2.19}
\end{equation*}
$$

Before examining the significance of the different terms in this expression, we shall demonstrate the equivalence of the forms of the Coulomb Green function
given by Perelemov and Popov and by Roberts.

The discussion is limited to the attractive Coulomb scattering of two particles of unit charge. We shall evaluate the scattered wave Green function $G^{(+)}$in the region of momentum space $p \cdot p^{\prime}>p e$, which for attractive scattering is the classically accessible region (Norcliffe et.al., 19694. Calculations of $G^{(t)}$ for the other regions of momentum space are similar, and can be inferred from the results of this calculation.

One can use the summation rule for the four-dimensional spherical harmonics to express the second term in Equation (2.13) in integral form. One obtains the expression(Peremov and Popov, 1965).

$$
\begin{equation*}
\frac{1}{2 \pi^{2}\left(\varepsilon-\varepsilon^{\prime}\right)^{2}}=\frac{-1}{4 \pi^{2} \sinh \omega} \int_{0}^{\infty} d \rho \operatorname{coth}(\pi \rho / 2) \sin (\rho \omega / 2) \tag{2.20}
\end{equation*}
$$

Substituting this equality back into equation (2.13) and using equation (2.6) we obtain the Coulomb Green function in momentum representation,
$G\left(f, f^{\prime} ; E\right)=\frac{-16 \mu_{12} p_{e}^{3} \delta\left(\varepsilon-\varepsilon^{\prime}\right)}{\left(p^{2}-p_{E}^{2}\right)^{2}\left(p^{12}-p_{E^{2}}\right)^{2}}$
$\frac{-16 \mu_{12} p_{E}^{3} 3}{4 \pi^{2} \sinh \omega\left(p^{2}-p_{E}^{2}\right)^{2}}\left[-1 / 2 \int_{-\infty}^{\infty} d \rho\right.$ cot $(\pi \rho / 2) \sin (\rho \omega / 2)$

$$
\begin{equation*}
\left.\left.+3 \int_{-\infty}^{\infty} d k \frac{k-\beta \operatorname{cothn} k}{k^{2}-\beta^{2}+i s} \sin k \omega\right] \frac{1}{\left(p^{12}-P E^{2}\right.}\right)^{2} \tag{2.21}
\end{equation*}
$$

The first term in this expression is equivalent to the $G_{0}$ of Equation $(2.16)$. The remaining integrals can be evaluated quite simply using contour integral methods and the residue theorem.

Consider the first term in the square brackets of Equation (2.21). The integrand has an infinite set of poles at $\sinh (\pi / / 2)=0$. We shall use the residue theorem to integrate the function $f(z)=\operatorname{coth}(\pi z / 2) \exp (i z \omega / 2)$ around the contour $C$ which is shown in Figure (2.1) along with a schematic representation of the poles of $f(z)$ lying within $C$. The poles of $f(z)$ are at $z=2 n i$ where $n$ is an integer $0 \leqslant n<\infty$ and each pole contributes a residue $(2 / \pi) \exp (-\cap \omega)$ to the integral. In the limit $R \rightarrow \infty$ the integral along the arc $\Gamma$ approaches zero (Spiegel, p.172), and the infinite set of poles contribute to the result

$$
\int_{-\infty}^{\infty} d \rho \sin (\rho \omega / 2) \text { coth }(n \rho / 2)=4 \sum_{n=0}^{\infty} \exp (-n \omega) \text { (2.22) }
$$

The integrand $k \sin k \omega /\left(k^{2}-3^{2}+i \delta\right)$ has two simple poles at $k= \pm\left(3^{-i \delta / 23}\right)$. The function $g(z)=z \exp (i z \omega) /\left(z^{2}-3^{2}+i \delta\right)$ has only one pole inside the contour $C_{1}$ of Figure (2.2) at $z=-3+i \delta / 23$, and using the residue theorem and taking the limit
$\delta \rightarrow 0 \quad$ (a specification of the analytic continuation for the Coriomb Green function) we obtain the result,

## FIGURE 2.1: The contour $C$

$x$ indicates poles of $f(z)=\operatorname{coth}\left(\frac{\pi z}{2}\right) \exp \left(i z \frac{\omega}{2}\right)$ lying within Contour C.

## FIGURE 2.2. The CONTOUR $C_{1}$

$x$ indicates poles of $g(z)=z \exp (i z \omega) /\left(z^{2}-B^{2}+i \delta\right)$. Only one pole lies within $C_{1}$.

FIGURE 2.3: THE CONTOUR $C_{3}$

$x$ indicates poles of $h(z)=\operatorname{coth}(\pi z) \exp (i z \omega) /\left(z^{2}-y^{2}+i \delta\right)$ lying within $C_{2}$

$$
\begin{equation*}
\int_{-\infty}^{\infty} \frac{k \sin k \omega}{k^{2}-\eta^{2}+i \delta} d k=\pi \exp (-i z \omega) \tag{2.23}
\end{equation*}
$$

Finally the integrand coth $(\Gamma k) \sin k \omega /\left(k^{2}-3^{2}+1 \delta\right)$ has an infinite set of poles at $k=n i$, and two simple poles at $k= \pm(3-i \delta / 23)$. Integrating the function $h(z)$ around the contour $C_{2}$ defined in Figure (2.3) we obtain the result

$$
\int_{-\infty}^{\infty} \frac{\text { ooh } \pi k \sin k \omega}{k^{2}-3^{2}+i \delta} d k=-2 \sum_{n=0}^{\infty} \frac{\exp (-n \omega)}{n^{2}+3^{2}}+\pi \operatorname{coth}(-\pi 3) \exp (-i \pi \omega)
$$

Using Equations (2.22) - (2.24) in Equation (2.21) we obtain the following expression for the Coulomb Green function in momentum representation

$$
\begin{align*}
G\left(p_{1}, \hat{p}^{\prime}, E\right)=G_{0} & +\frac{8 \mu_{12} p_{E}^{3} B}{\pi \sinh \omega} \frac{1}{\left(p^{2}-p_{E}^{2}\right)^{2}}\left[\frac{1}{\pi} \sum_{n=0}^{\infty} \exp (-n \omega) \frac{n^{2}}{n^{2}+3^{2}}+\right. \\
& \left.\left.+z \exp (-i z \omega) \frac{\exp (-2 \pi z)}{1-\exp (-2 \pi z)}\right] \frac{1}{\left(p^{12}-p_{E}^{2}\right.}\right)^{2} \tag{2.25}
\end{align*}
$$

Using the equality

$$
\sum_{n=0}^{\infty} \exp (-n \omega) \frac{n^{2}}{n^{2}+\eta^{2}}=\sum_{n=0}^{\infty} \exp (-n \omega)-3^{2} \sum_{n=0}^{\infty} \frac{\exp (-n \omega)}{n^{2}+3^{2}} \text { (2.26) }
$$

and the transformations between $\mathcal{E}$-space and $p$-space given by Perelemov and Popov, we can write for the first term in the square brackets,

$$
\begin{align*}
\frac{3}{2 \pi^{2} \sinh \omega} \sum_{n=0}^{2} \exp (-n \omega) \frac{n^{2}}{n^{2}+3^{2}}=\frac{3}{8 \pi^{2} p} \frac{\left(p^{2}-p E^{2}\right)\left(p^{\prime 2}-p E^{2}\right)}{\left|p-p^{\prime}\right|^{2}} & = \\
& -\frac{3^{3}}{4 \pi^{2} \sinh \omega} \sum_{n=-\infty}^{\infty} \frac{\exp (-|n| \omega)}{n^{2}+3^{2}} \tag{2.27}
\end{align*}
$$

Hence the Coulomb Green function is given by

$$
\left.-\frac{3^{3}}{4 \pi^{2} \sinh \omega} \sum_{n=-\infty}^{\infty} \frac{\exp (-\ln \mid \omega)}{n^{2}+3^{2}}+\frac{3^{2}}{2 \pi \sinh \omega} \frac{\exp (-i \sin ) \exp (-2 \pi \xi)}{1-\exp (-2 \pi 3)}\right]^{28)}
$$

This is similar in form to the expressions (2.16) and (2.17a) of Roberts, the differences being due to the different definitions of $B$ and $\nu$ for attractive scattering. Perelemov and Poor define 3 to be negative for attractive scattering (Equation (2.8)), wheras $v$ is positive for both the repulsive and the attractive case (Equation (2.19)), and noting that the first term in the square brackets of (2.28) is just $G_{1}$ of (2.16), we see that Perelemov and Popov's form of the Coulomb Green function for $\mathbf{E}>0$ and $\quad P_{1} p^{\prime}>p E$ is exactly the same as the form (2.16) derived by Roberts, if we redefine $3^{\text {as }}-\nu$. We note that the transformation $3 \rightarrow-\nu$ could be carried out at the beginning of the analysis in (2.13) and (2.146). In this case care must be exercised in the analytic continuation, and the sign of $\delta$ in the denominator of the integrand of Equation (2.14b) is changed. . Then the results (2.16) and (2.173) of Roberts are directly obtained after an analysis similar to the one we have performed.

#### Abstract

Using Equations (2.14c) and (2.14d) and the same method of analysis one can obtain the equivalent results (2.17b) and (2.17c) of Roberts for the other regions of momentum space.

Therefore the method of Perelemov and Popov in which the Coulomb Green function is evaluated for $E<0$ and aralytically continued to give $G^{(t)}$ for $E>0$ is shown to be equivalent to the method of Roberts in which $G^{( \pm)}$is calculated directly for $E>0$. Chen and Chen (1972) have demonstrated the equivalence of the form of $G^{( \pm)}$derived by Perelmov and Popov with the forms derived by Schwinger (1964), Hostler (1964) and Okubo and Feldman (1960) which implies that the Roberts expression is equivalent to all of these forms. The Roberts form of $G^{( \pm)}$is such that it can be partially expressed as a sum over classical paths, and it is this form which we will concern ourselves with in this thesis.

The Coulomb Green function is analytic everywhere in the complex energy plane apart from the physical energy spectrum. It is singular at the bound state energy levels for $E<0$, and along the continuum cut representing the energy continuum for $E>0$. These properties have important consequences for the two-body off-shell Coulomb $T$ matrix and will be considered in more detail in the following sections.

### 2.3 The Spectral Operator

A correspondence identity for the spectral operator, $\delta(E-H)$, for positive energy Coulomb scattering has been demonstrated by Norcliffe et.al. (1769N. The diagonal elements of the kernel of the spectral operator in momentum represervation are proportional to the quantal microcanonical momentum distribution $p_{E}^{a m}(p)$. Evaluating this quantity from our results for $G^{( \pm)}$in the classical limit and comparing it with the classical microcanonical momenimistribution $p_{e}^{c m}(q)$ provides a useful check on our results.

From (2.16) and (2.17a) - (2.17c) we have for the spectral operator
$\left.\left.\left.\langle p| \delta(E-H)\right|_{f^{\prime}}\right\rangle=\left.\frac{1}{2 \pi i}\langle f|\left(G^{(-)}-G^{(+)}\right)\right|_{f} ^{\prime}\right\rangle$ $=\frac{8 \mu_{12}^{3} p_{E} k^{2} g(\nu)}{\pi^{2} \hbar^{2}\left(p^{2}-p_{E}^{2}\right)^{2}\left(p^{\prime 2}-p_{E}^{2}\right)^{2}(1-\exp (-2 \pi \nu))} \frac{\sin \nu \omega}{\sin h \omega}(2.29)$
where $k$ is given by $k=z_{1} z_{2} e^{2}$
and

$$
\begin{aligned}
& \qquad \begin{array}{l}
1 \text { for } p_{1} p^{\prime}>p_{E} \\
3^{(\nu)}=- \\
\\
\left.\exp p(-\pi \nu) \text { for } p>p_{E}, p^{\prime}<p_{E} \text { or } p<p_{E}, p^{\prime}>p_{E}\right) \text { for } p_{1} p^{\prime}<p_{E}
\end{array} \\
& \text { Banks (Norcliffe et.al., 1969\| has calculated } p_{E}^{\text {cm }}(q) \\
& \text { normalised to unit inward flux, and for attractive }
\end{aligned}
$$ scattering the result is

$$
p_{E}^{(M 1)}(p)=\frac{64 \pi k^{3} \mu_{2}^{4}}{p_{E}^{2}\left(p^{2}-p_{E}^{3}\right)^{4}} \times \begin{aligned}
& 1 \text { for } p>p_{E} \\
& \text { ofor } p\langle p E
\end{aligned}
$$

Taking the limit $f^{\rightarrow \rightarrow} f^{\prime}$ of Equation (2.29) and using the same normalisation as in the classical evaluation, Norcliffe et.al. obtained the following expression for $p_{E}^{q m}(p)$,

From Equation (2.19) we see that $\nu$ is proportional to $\hbar^{-1}$ and in the classical limit when $\hbar \rightarrow 0$ then
$\nu$ becomes infinite. Equivalently we could say that
$\nu$ is infinite for large principle quantum number, $n$. In this limit Equation (2.32) reduces to Equation (2.31). Thus the classical limit of $p_{e^{q m}}(f)$ derived from our results agrees exactly with the classical result.

Dividing the momentum space as shown in Figure (2.4), then the region III, where $P_{1} p^{\prime}<P_{E}$, is classically inaccessible for attractive Coulomb scattering, and this is confirmed by the fact that $p_{E}^{c m}(f)=0$ in this region. Quantum mechanically, barrier penetration into region III is a possibility, this fact being indicated by the ron-zero momentum distribution for the $p<p \in$ region in (2.32). However on taking the

## FIGURE 2.4

The classical picture of momentum space for attractive scattering.
classical limit of (2.32), the effects of barrier penetration are seen to disappear and the classical result (2.31) is obtained.

## 2. The Could $\mathrm{m}^{3} T$ matrix

Substituting the expression for the scattered wave Coulomb Green function (2.25) into Equation (2.3), we obtain the form for the $T$ matrix
$\left.\left.\langle p| T(E)\right|_{f} ^{\prime}\right\rangle=\frac{4 p_{E}^{3} 3}{2 \pi \mu_{12}} \frac{1}{\left(p^{2}-p_{E}^{2}\right)\left(p^{12}-p E^{2}\right)} \times$

$$
\begin{equation*}
x\left[\frac{3 \exp (-i z \omega)}{\sinh \omega} \frac{\exp (-2 \pi \beta)}{1-\exp (-2 \pi \beta)}+\frac{1}{\pi} \sum_{n=0}^{\infty} \frac{\exp (-n \omega)}{\sinh \omega} \frac{n^{2}}{n^{2}+z^{2}}\right] \tag{2.33}
\end{equation*}
$$

This is exactly equivalent to the expression derived by Shastry and fiajagopal (1972) for the region $p, p^{\prime}>P E$. For the other regions of momentum space a similar analysis reproduces the results of Shastry and Rajagopal. The analysis of Chen and Chen (1972) implies the equivalence of Equation (2.33), and its extension to the rest of momentum space, with the various other forms of the Coulomb $T$ matrix cited by Chen.

An alternative form is obtained by substituting the Roberts form of the scattered wave Coulomb Green function (2.16) and (2.17a-c) in Equation (2.3). Then th i Coulomb $T$ matrix can be expressed as a sum of three terms (Roberts, 1971)

$$
\begin{equation*}
\langle p| T(E)\left|p^{\prime}\right\rangle=T_{B}+T_{p}+T_{c} \tag{2.34}
\end{equation*}
$$

where

$$
\begin{gather*}
T_{B}=\frac{-q}{\left.2 \pi^{2} \mu_{12}\right|_{f}-\left.p^{\prime}\right|^{2}}  \tag{2.35a}\\
T_{p}=\frac{p^{3}}{4 \pi^{2} \mu_{2}^{3}|E-T|\left|E-T^{\prime}\right| \sinh \omega} \sum_{n=-\infty}^{\infty} \frac{\xi^{n} \exp (-|n| \omega)}{n^{2}+\nabla^{2}} \quad(2.35 b) \\
T_{c}=\frac{-p_{c}^{3} 3\left(T_{1} T^{\prime}\right) \exp (i \nu \omega)}{2 \pi \nu \mu_{12}^{3}|E-T| E-T^{\prime} \mid(1-\exp (-2 n \nu)) \sinh \omega} \quad(2.35 c) \\
\text { where } \quad p_{c}=\left|z_{1} z_{2}\right| e^{2} \mu_{12} / \hbar, T=P^{2} / 2 \mu_{121} T^{\prime}=p^{\prime 2} / 2 \mu_{12}
\end{gather*}
$$

and

$$
\begin{align*}
& \text { For } T_{1} T^{\prime}>E \\
& 3\left(T, T^{\prime}\right)=\exp (-\pi \nu) \text { for } T>E_{1} T^{\prime}<E \text { or } T\left\langle E, T^{\prime}\right\rangle E \\
& \exp (-2 \pi v) \text { for } T_{1} T^{\prime}<E \tag{2.36}
\end{align*}
$$

$$
\xi^{\prime}=\operatorname{sign}(E-T)\left(E-T^{\prime}\right)
$$

$T_{B}$ is just the first Born approximation to the $T$ matrix given by Equation (1.5). $T_{f}$, which we call the pole term, is related to the bound state poles of the Coulomb Green function. At negative energies singularities appear in $T_{p}$ for $n= \pm \nu$ which correspond to the bound state energy levels of the hydrogen atom. The third term, $T_{C}$, contains a factor $g\left(T_{1} T^{\prime}\right)[1-\exp (-2 n 0)]^{-1} \exp (i v \omega)$ which Norcliffe et.al. (1969) have shown can be expressed as a sum over classical paths. $T_{c}$ is thus called the classical path term.

The classical paths are defined in the normal sense only in the classically accessible region I of

Figure (2.4). In this region the path connecting the momenta $f$ and $f^{\prime}$ contributes to $T_{c}$ an amount proportional to the cosine (sine) of the classical action in units of $\hbar$ along the path. Norcliffe et.al. (195\%) show that
$\frac{-v^{2}}{2 \pi \sinh \omega} \frac{\exp (i v \omega)}{1-\exp (-2 \pi \nu)}=\nu^{2} \sum_{c=0}^{\infty} \frac{\exp \left[i S_{c}\left(p, p^{\prime} j \in\right) / \hbar\right]}{2 \pi \sin \left(\text { ana lyric } f^{\operatorname{ahn}} \operatorname{lengh}\right)}(2.37)$ where $S_{c}$ is the classical action for $c$ complete orbits from $f$ to $f^{\prime}$. For the case where the path is directly alone the arc from $\underset{q}{ }$ to $\frac{p^{\prime}}{f}$ the action is

$$
\begin{equation*}
S_{0} \equiv \int_{q^{\prime}}^{f} \underline{r} \cdot d q^{\prime \prime} \tag{2.38}
\end{equation*}
$$

In analogy with barrier penetration in the quantum mechanical case, classical paths may exist in the classically inaccessible region III, but not in the normal sense. The paths are the analytic continuations of the classically allowed paths and an infinite number of these paths may connect any two points $f$ and $f^{\prime}$ within or without the classically accessible region.

The real significance of Equation (2.34) lies in its on-shell limit when $T_{1} T^{\prime} \rightarrow E$. The scattering amplitude $f(E, \theta)$ for scattering at an energy $E$ through an angle $\theta$ for short range' potentials is proportional to the on-shell limit of the $T$ matrix. Hence taking the on-shell limit of each term in Equation (2.32) will
give us an expression which car be compared with the scattering amplitude. It is found (Roberts, 1971) that the on-shell limits of $T_{B}$ and $T_{p}$ are Equal and opposite. Thus the scattering amplitude is to be compared with the on-shell limit of a term which may be expressed as a sum over classical paths.

Ford (196\%) and Schwinger (1964) have demonstrated that the on-shell limit of the Coulomb $T$ matrix does not exist in a strictly mathematical sense due to the lone range nature of the Coulomb potential. However, Schwinger ( 1964 ) has shown that if the free wave Green function in Equation (2.3) is replaced near the energy shell by the distorted wave Green function, $\left.\tilde{G}_{0}^{( }\right)$ which accounts for the Coulomb distortion, then the Rutherford scattering amplitude is obtained from the on-shell limit of $T_{c}$. This on-shell correspondence identity leads to the possibility that cross sections in atomic scattering processes can be expressed in terms of a sum over classical paths.

### 2.5 The $E<0$ Coulomb $T$ matrix

The $T$ matrix we have dealt with so far is the positive energy $T$ matrix. Contributions from the $E<O$ Coulomb $T$ matrix are not of much concern to us in scattering calculations, however in certain cases they are relevant. We therefore quote the results obtained by Roberts (private communication) for the $E<0 T$ matrix which can be evaluated directly from the

Give us an expression which car be compared with the scattering amplitude. It is found (Roberts, 1971) that the on-shell limits of $T_{B}$ and $T_{p}$ are equal and opposite. Thus the scattering amplitude is to be compared with the on-shell limit of a term which may be expressed as a sum over classical paths.

Ford (1761:) and Schwinger (1964) have demonstrated that the on-shell limit of the coulomb $T$ matrix does not exist in a strictly mathematical sense due to the lon range nature of the Coulomb potential. However, Schwinger (1964) has shown that if the free wave Green function in Equation (2.3) is replaced near the energy shell by the distorted wave Green function, $\tilde{G}_{0}^{(t)}$, which accounts for the Coulomb distortion, then the Rutherford scattering amplitude is obtained from the on-shell limit of $T_{c}$. This on-shell correspondence identity leads to the possibility that cross sections in atomic scattering processes can be expressed in terms of a sum over classical paths.

### 2.5 The E<O Coulomb $T$ matrix

The $T$ matrix we have dealt with so far is the positive energy $T$ matrix. Contributions from the $E<O$ Coulomb $T$ matrix are not of much concern to us in scattering calculations, however in certain cases they are relevant. We therefore quote the results obtained by Roberts (private communication) for the $E<O T$ matrix which can be evaluated directly from the
$E<0$ Coulomb Green function representation of Perelemzv and Popov. For attractive scattering we have $\left\langle\left. p \pi(E)\right|_{f^{\prime}}\right\rangle=\frac{P^{3}}{2 \pi^{2} \mu_{12}^{3}(E-T)\left(E-T^{\prime}\right) \sin X} \times$

$$
\times\left[\int_{0}^{\infty} \frac{\sinh (\pi-x) k d k}{\left(k^{2}+\nu^{2}\right) \sinh \pi k}-\frac{i \pi \sin \nu x}{v} \sum_{k=-\infty}^{\infty} \cos 2 \pi v c\right] 2.391
$$

where $\mathcal{X}$ is defined in Section(2.2). The second term, which is omizted in the Perelemov and Popov representation, is due to the fact that for attractive scattering when $\nu=-3$ is positive the $\Phi(z, V)$ of Equation (2.11) an be singular. Perelemov and Popov have just considered the principle pert of this function and have omitted the $\delta$-function wisich is associated with the sineularity.

For repulsive scattering $\Phi(z, v)$ has no singularities and we obtain straigit forwardly for the repulsive seavtering E<O Coulonb $T$ matrix
$\langle p| T(E)\left|f^{\prime}\right\rangle=\frac{-p^{3}}{2 \pi^{2} \mu_{1}^{3}(E-T)\left(E-T^{\prime}\right) \sin x} \int_{0}^{\infty} \frac{\sinh (\pi-x) k d k}{\left(k^{2}+v^{2}\right) \sinh \pi k}(2 . \dot{0})$
2.5 Propertin3 of the two-body off-shell joulomb $T_{\text {matrix }}$
A compreinensive an: orat of the properties of the Coulomb T matrix has been given in the review of Chen and Chen (1972), so here we will just briefly mention the properties winisil concera us most.

The Coulomb $T$ machine, like the Gre $n$ function, is analytic everywhere in the complex energy plane apart from the bound state poles and the continuum edt. It is define t on dinner side of the continuum out and several authors (Chen and Chen, 1972, Nuttall and SEacat, 2071) have demonstrated that it satisfies. a modified unitarity relation. Indeed Robert.; (1971) has demonstrated that the unitarity relation is related to the spectral operator and thus to classical paths by (note error in Roberts' result)
$\langle f|\left(T-T^{+}\right)\left|f^{\prime}\right\rangle=-(2 \pi i)(E-T)\left(E-T^{\prime}\right)\langle p| \delta(E-H)\left|p^{\prime}\right\rangle(2.41)$
We have already meri=ioned that the Coulomb $T$ matrix has singularities on the energy shell. It also has singularities on the half-energy shell, that is when $T \rightarrow E$ or $T^{\prime} \rightarrow E$. These singularities lead to the factors $\left.g^{( } T_{1} T^{\prime}\right)$ in the expression for $T_{C}$. In practical applications great care must be taken with these factors on integrating the $T$ matrix over the momentuin variables.
2.7 Summary

To conclude this chapter we summarise the results for the form of the two-body off-shell Coulomb $T$ matrix which we shall utilise in the Faddeev equations to solve several atomic collision problems in the next two chapters.
i) Attractive scattering

$$
1+\frac{\left.2 p E^{2}\right|_{p}-\left.p^{\prime}\right|^{2}}{\left(p^{2}-p_{E}^{2}\right)\left(p^{\prime 2}-p_{E^{2}}\right)}=+\cosh \omega \text { for } T_{1} T^{\prime}>E \text { and } T_{1} T^{\prime}<E
$$

ii) Repulsive scattering

For the case of repulsive scattering we must change the sign of the Coulomb interaction factor $p_{c}$.
The results then become

$$
\begin{gather*}
\left.\left.\left.\langle f| T(E)\right|_{f}\right\rangle\right\rangle=\cdot T_{B}+T_{f}+T_{C} \\
T_{B}=\frac{p_{C}}{2 \pi^{2} \mu_{12}\left|p-f^{\prime}\right|^{2}} \tag{2.42a}
\end{gather*}
$$

$$
\begin{aligned}
& \left.\left.\langle f| T(E)\right|_{f} ^{\prime}\right\rangle=T_{B}+T_{p}+T_{C} \\
& T_{B}=\frac{-p_{c}}{2 \pi^{2} \mu_{12}\left|p-p^{\prime}\right|^{2}} \\
& T_{P}=\frac{P_{c}^{3}}{4 \pi^{2} \mu_{12}^{3}|E-T|\left|E-T^{\prime}\right| \sinh \omega} \sum_{n=-\infty}^{\infty} \frac{\xi^{n} \exp (-\ln \mid \omega)}{n^{2}+\nu^{2}} \\
& T_{c}=\frac{-P_{c}^{3}}{2 \pi \nu \mu_{12}{ }^{3}|E-T|\left|E-T^{\prime}\right| \sinh \omega} \quad \frac{B\left(T_{1} T^{\prime}\right) \exp (i v \omega)}{\mid-\exp (-2 \pi \nu)} \\

& \nu=p_{E} / p_{E}, \quad p_{C}=-\left|z_{1} z_{2}\right| e^{2} \mu_{12} / \hbar
\end{aligned}
$$

and $W$ is defined the same as in the attractive case. For repulsive scattering the classically accessible region is region III where $p_{1} p^{\prime}<P_{E}$

## THE ELASTIC e-H SCATTERING PROBLEM

### 3.1 Introdustion

Ore of the most fundamental three-body processes in atomic collisior physics is the elastic scatterirg of electrons by atomic hydrogen in its ground state. This direct collision process is represerted by

$$
\begin{equation*}
1+(2,3) \longrightarrow 1+(2,3) \tag{3.1}
\end{equation*}
$$

where 1 is the incident electror, and we designate 2 to be the bound electron and 3 to be the proton.

The trarsition amplitude for the process (3.i) is the matrix element $\langle f| T_{D}|i\rangle$ where $|i\rangle$ and $|f\rangle$ represert respectively the initial and final 'freé states of the system. In the first order iterate of the Faddeev equations the three-body $T$ operator, $T_{D}$, is the sum of two terms, $T_{2}$ and $T_{3}, T_{2}$ is the two-bcdy off-shell Coulomb $T$ operator in the three-particle Hilbert space for the interaction between the incident electron and the proton, with the bound electron as a spectator particle, and similarly $T_{3}$ represerits the incidert electron interaction with the bound electron. The expressions for the two-body off-shell CoulombTmatrix (Equatiors (2.34) (2.36), (2.42)) will be utilised to calculate the transitior amplitude.

The scattering amplitude, $f(E, \theta)$, for the $e-H$ scattering process is given in terms of the transition amplitude by (Newton., p.219)

$$
\begin{equation*}
F(E, \theta)=-4 \pi^{2} \mu_{1}\langle F| T_{D}|i\rangle \tag{3.2}
\end{equation*}
$$

$w_{h}$ ere $\mu_{1}$ is the mass of particle 1 , the incident electron, reduced relative to the centre of mass of the $(2,3)$ particle system. The scattering amplitude is complex and the differential cross section, $d \sigma / d \Omega$, is given by

$$
\begin{equation*}
\frac{d \sigma}{d \Omega}=|F(E, \theta)|^{2} \tag{3.3}
\end{equation*}
$$

The asymptotic momentum of the incident electron is $q_{i}$ initially and $q_{f}$ finally. The energy conservation relation for the system is

$$
\begin{equation*}
E_{i}+q i^{2} / 2 \mu_{1}=E_{F}+q F^{2} / 2 \mu_{1} \tag{3.4}
\end{equation*}
$$

where $E_{i}$ and $E_{f}$ are respectively the initial and final bound state energies of the hydrogen atom. For the case of elastic scattering from the ground state $\left|q_{i}\right|=\left|q_{q}\right|$, and $E_{i}=E_{F}=E_{13}=-\beta^{2} / 2 \mu_{23}$, where $p_{0}$ is the Bohr momentum for the ground state of hydrogen and $\mu_{23}$ is the reduced mass of the $(2,3)$ two-particle system.

The Faddeev equations and the derived forms of the two-body off-shell Coulomb $T$ matrix are in the momentum representation. It is therefore convenient to work in the barycentric coordinate system which is described in the next section.
3.2 The Barycentric Coordinate Systems

The collision process is shown schematically in Figure (3.1). The transition amplitude is $\langle F| T_{0}^{\prime}|i\rangle$
$\stackrel{\rightharpoonup}{e_{1}^{-}}$

## FIGURE 3.1

and the initial and final 'free' states are given in the barycentric coordinates appropriate to the initial conditions by

$$
\begin{align*}
& \left\langle\underline{p}_{q_{1}} q_{3} \mid i\right\rangle=\delta\left(\underline{p}-p_{i}\right) \delta\left(q_{1}-q_{i}\right) \phi_{15}\left(q_{23}\right) \\
& \left\langle\underline{p} q_{1} q_{u} \mid f\right\rangle=\delta\left(\underline{p}-\underline{p}_{F}\right) \delta\left(q_{1}-q_{F}\right) \phi_{15}\left(q_{23}\right) \tag{3.5b}
\end{align*}
$$

The barycentric coordinate relations to the laboratory coordinates are shown in Figure (3.2). The total momentum vector of the system is $P$, the subscript
$i$ and $f$ indicating respectively its initial and final values. The coordinate $q_{1}$ is the momentum of $e_{1}^{-}$ relative to the centre mass of the $(2,3)$ system, and $q_{23}$ is the relative momentum of $e_{2}^{-}$and $p_{3}^{+}$in their own centre of mass frame. The coordinates $q_{1}$ and $q_{2 s}$ are conjugate momenta and a cyclic permutation of the subscripts is allowed depending on the initial conditions (Chen ct.al., 1969), so that the states $|i\rangle$ and $|F\rangle$ could equally be defined on the $\left|\rho q_{2} q_{31}\right\rangle$ basis or the $\left.\| f q_{s} q_{12}\right\rangle$ basis. The $\delta\left(q_{1}-q_{i}\right)$ factor in Equation (3.5a)

represents an initial plane wave state for the incident electron in the momentum representation, while $\phi_{1 s}(q)$ is the ground state wave function of the hydrogen atom in momentum space. The total energy, $E$, of the system is

$$
\begin{equation*}
E=\frac{P_{i}^{2}}{2 M}+\frac{q i^{2}}{2 \mu_{1}}+E_{1 S} \tag{3.6}
\end{equation*}
$$

where $M$ and $\mu_{1}$ are defined in Figure (3.2).

The matrix elements $\langle f| T_{2}|i\rangle$ representing the electron-proton contribution to the scattering amplitude and $\langle F| T_{3}|i\rangle$ represerting the electronelectron contribution are evaluated separately. The momentum representation of $T_{2}$ using the appropriate barycentric coordinates is
$\left\langle\underline{p} q_{2} q_{31}\right| T_{2}(E)\left|\underline{p}^{\prime} q_{2}^{\prime} q_{31}^{\prime}\right\rangle$

$$
\left.=\left.\delta\left(\underline{p}-p^{\prime}\right) \delta\left(q_{2}-q_{2}^{\prime}\right)\left\langle q_{31}\right| T_{2}\left(E-\frac{p^{2}}{2 M}-\frac{q_{2}^{2}}{2 \mu_{2}}\right)\right|_{q_{31}}\right\rangle_{(3.7)}
$$

Physically $\delta\left(\underline{P}-P^{\prime}\right)$ implies the conservation of total momentum; we will work from now in the full barycentric frame where $P$ is taken to be zero. The $\delta\left(q_{2}-q_{n^{\prime}}^{\prime}\right)$ factor indicates the conservation of momentum of the bound electron as this is considered to be a spectator particle in the electron-proton interaction. The matrix element $\left\langle q_{31}\right| T_{2}(\varepsilon)\left|q_{31}{ }^{\prime}\right\rangle$ is the two-body off-shell Coulomb $T$ matrix of particles 1 and 3 in their own two-body centre of mass frame, and we note
that the ceritre of mass energy $\mathcal{E}$ is dependent on the kinetic energy of particle 2 (Ahmadzadeh ard Ton, 1965).

Using Equations (3.7) and (3.5a,b) we obtain for $\langle F| T_{2}(E)|i\rangle$, $\langle F| T_{2}(E)|i\rangle=\int \cdots \int d q_{1} \cdot d q_{1}^{\prime} d q_{23} d q_{23}{ }^{\prime}\left\langle F \mid q_{1} q_{23}\right\rangle \times$
$x\left\langle q_{1} q_{23}\right| T_{2}(\varepsilon)\left|q_{q^{\prime}} q_{23}\right\rangle\left\langle q_{1^{\prime}} q_{23}^{\prime} \mid i\right\rangle$
$=\int \cdots \cdot \int d q_{1} d q_{1}^{\prime} d q_{23} d q_{23}^{\prime} \delta\left(q_{1}-q_{p}\right) \phi_{1 s^{*}}{ }^{*}\left(q_{23}\right) \times$
$\times \delta\left(q_{2}-q_{2}{ }^{\prime}\right)\left\langle q_{33}{ }^{\prime}\right| T_{2}\left(E-\frac{q_{2}^{2}}{2 u_{2}}\right\rangle\left|q_{3_{3}}\right\rangle \delta\left(q_{1}^{\prime}-q_{i}\right) \phi_{15}\left(q_{23}^{\prime}\right)$,

The integrations over $q_{1}$ and $q^{\prime}$ are trivial leading to the result that $q_{\prime}=q_{f}$ and $q_{L^{\prime}}^{\prime}=q_{i}$ throughout the remainder of the integrand. To further reduce the number of variables we can express $q_{2}$ in terms of $q_{23}, q_{i}$ and $q_{f}$ by using relations from Figure (3.2) and the fact that for the $\underline{P}=0$ barycentricsystem $q_{i}=f_{i}(i=1,2,3)$. We obtain the coordinate relation

$$
\begin{equation*}
q_{2}=q_{23}-\frac{m_{2}}{m_{2}+m_{3}} q_{F} \tag{3.9a}
\end{equation*}
$$

and

$$
\begin{equation*}
q_{2}-q_{2}^{\prime}=q_{23}-q_{22} 3^{\prime}+\frac{m_{2}}{m_{2}+m_{3}} \Delta q \tag{3.9b}
\end{equation*}
$$

where $\Delta q_{i}=q_{i}-q_{i}=2\left|q_{i}\right| \sin \theta / 2$
is the momentum.transfer for elastic scattering through an angle $\theta$. We can therefore perform the integration over $q_{23}{ }^{\prime}$ and obtain the relation

$$
\begin{equation*}
q_{23}^{\prime}=q_{23}+\frac{m_{2}}{m_{2}+m_{3}} \frac{\Delta q}{q} \tag{3.10}
\end{equation*}
$$

The mass of the proton $m_{3}$ is of the order of $10^{3}$ times greater thar. the mass of the electron, $m_{2}=m_{e}$, so we may take the limit $m_{3} \rightarrow \infty$ without losing substantial accuracy. This limiting process is equivalent to considering the proton to be stationary during the collision, ard is a standard approximation for the electror-hydrogen problem. In this limit with the use of Equations (3.8) and (3.10) and the expression for $q_{31}$ from Figure (3.2), the matrix element
$\langle F| T_{2}(E)|i\rangle \quad$ reduces to an integration over one momentum vector,
$\langle F| T_{2}(E)|i\rangle$

$$
\begin{equation*}
=\int d q_{2} \phi_{1 s}^{*}\left(q_{2}\right) \phi_{v}\left(q_{2}\right)\left\langle q_{F}\right| T_{2}\left(E-\frac{q_{2}^{2}}{2 m_{e}}\right)\left|q_{i}\right\rangle \tag{3.11}
\end{equation*}
$$

The calculation for the electron-electron contribution is similar to the above and the analogue of Equation (3.8) is
$\langle f| T_{3}(E)|i\rangle=\int \cdots \int d q_{1} d q_{1}^{\prime} d q_{23} d q_{23}^{\prime} \delta\left(q_{1}-q_{f}\right) \phi_{1 s^{\prime}}{ }^{\prime}\left(q_{23}\right) \times$ (3.12)
$\left.\times\left.\delta\left(q_{3}-q_{3^{\prime}}\right)\left\langle q_{q^{2}}\right| T_{3}\left(E-\frac{q_{3}^{2}}{2 q_{3}}\right)\right|_{q_{12}^{\prime}}\right\rangle \delta\left(q_{1^{\prime}}-q_{i}\right) \phi_{v}\left(q_{23}^{\prime}\right)$
where we now have the coordinate relations

$$
\begin{equation*}
q_{3}=-\frac{m_{3}}{m_{2}+m_{3}} q_{1}-q_{23} \tag{3.13}
\end{equation*}
$$

Again the integrationsover $q_{1} \cdot q_{1}^{\prime}$ and $q_{2}^{\prime}$ can be performed trivially and in the limit $m_{3} \rightarrow \infty$ we obtain for $\left\langle F^{\prime}\right| T_{3}(E)|i\rangle$
$\langle F| T_{3}(E)|i\rangle$
$=\int d q_{23} \phi_{15}{ }^{*}\left(q_{3}+q_{F}\right) \phi_{v}\left(q_{3}+q_{i}\right)\left\langle q_{F}+\frac{1}{2} q_{3}\right| T_{3}\left(E-\frac{q_{3}^{2}}{4 m_{k}}\right)\left|\begin{array}{c}(3.14) \\ q_{i}\end{array} \frac{1}{2} q_{3}\right\rangle$

In Equations (3.11) and (3.14) we must substitute the expressions for the attractive and the repulsive twobody off-shell Coulomb $T$ matrices respectively. We have been mainly concerned with the $T$ matrix for positive energy $\varepsilon>0$, i.e. for the regions $q_{2^{2}}<2 m_{e} E$ in Equation (3.11) and $9_{3}{ }^{2}<4 m_{e} E$ in (3.14). For the remaining regions of $\left|q_{2}\right|$ and $\left|q_{3}\right|$ space we must use the $\varepsilon<0$ form of the Coulomb $T$ matrix given by Equations (2.39) and (2.40). For example, Equation (3.11) must be divided into two integrals $\langle F| T_{2}(E)|i\rangle$

$$
\begin{align*}
&=\left.\int_{0\langle | q_{2} \mid<\left(2 m_{e} E\right)^{\prime / 2}} d \phi_{1} s^{*}\left(q_{2}\right) \phi_{1}\left(q_{2}\right)\left\langle q_{F}\right| T_{2}(\varepsilon\rangle 0\right)\left|q_{i}\right\rangle  \tag{3.15}\\
&+\int d q_{2} \phi_{1 s}^{*}\left(q_{2}\right) \phi_{1 s}\left(q_{2}\right)\left\langle q_{F}\right| T_{2}(\varepsilon<0)\left|q_{i}\right\rangle \\
&\left(2 m_{e} E\right)^{1 / 2} \leqslant\left|q_{2}\right|<\infty
\end{align*}
$$

For the scattering problem, where $\varepsilon>0$, it is to be expected that the second integral is negligible and we shall ignore this contribution in most of our calculations. In fact, the insignificance of this integral can be demonstrated numerically for the physical processes we consider (Roberts, private communication). The same arguments hold for $\langle F| T_{3}(E)|i\rangle$.

We are mostly interested in contributions to $\langle F| T_{2}(E)|i\rangle$ and $\left\langle\mathrm{Fi}_{3}(E) \mid i\right\rangle$ from the classical path part of the $T$ matrix, $T_{c}$, so in, the next section we shall evaluate $\langle F| T_{2}{ }^{c}(E)|i\rangle$ and $\langle F| T_{3}{ }^{c}(E)|i\rangle$ where the
c superscript indicates that the classical path term of the two-body $T$ matrix has been used. In later sections we shall evaluate contributions from the Born and pole terms of the $T$ matrix.
a) the elcctror-broton term $\langle f| T_{2}^{c}(E)|i\rangle$

The electron-proton contribution to the scattering matrix, $\langle F| T_{2}^{c}(E)|i\rangle$, is relatively simple to calculate and reduces to a one-dimensional. integral. The interaction is attractive so we make use of Equation (2.35) for $T_{c}$. The choice of the factor $Z\left(T_{1} T^{\prime}\right)$ depends on the sign of $(T-\varepsilon)$ and $\left(T-\varepsilon^{\prime}\right)$. From Equations (3.4), (3.6) and (3.7) we have for the electron-proton interaction,

$$
\begin{equation*}
T-\varepsilon=\frac{q_{31}^{2}}{2 \mu_{31}}-\left(\frac{q_{F}^{2}}{2 \mu_{1}}-\frac{p_{0}^{2}}{2 \mu_{23}}-\frac{q_{2}^{2}}{2 \mu_{2}}\right) \tag{3.16}
\end{equation*}
$$

which because of the equivalence of the pairs of conjugate momentum variables car be written.

$$
T-\varepsilon=\frac{1}{2 \mu_{23}}\left(q_{23^{2}}+p_{0}^{2}\right)=\frac{1}{m_{3} \rightarrow \infty}=\frac{1}{2 m_{e}}\left(q_{23}^{2}+p_{0}^{2}\right)(3.16 a)
$$ Therefore $(T-\varepsilon)$ is positive and we can similarly show that $\left(T^{\prime}-\varepsilon\right)$ is also positive, so that $B\left(T T^{\prime}\right)=1$ must be chosen in the expression for $T_{c}$. We also note that this implies that the electron-proton paths all lie in the classically accessible region of momentum space.

Taking the limit $m_{3} \rightarrow \infty$ we therefore have for $T_{c}$

$$
\begin{equation*}
T_{c}=\frac{-p_{0}^{3} \exp (i v \omega)}{2 \pi \nu m_{e}^{3}|\varepsilon-T|\left|\varepsilon-T^{\prime}\right|(1-\exp (-2 \pi \nu)) \sinh \omega} \tag{3.17}
\end{equation*}
$$

where from (3.9a) and (3.16a)

$$
\begin{equation*}
|\varepsilon-T|=\left|\varepsilon-T^{\prime}\right|=\frac{1}{2 m_{e}}\left(q_{2}^{2}+p_{0}^{2}\right) \tag{3.18}
\end{equation*}
$$

From the definition for $\nabla$ and $u$ for attractive scattering we have

$$
\begin{equation*}
\nu=\frac{p_{0}}{\left(2 m_{e} E-q_{2}^{2}\right)^{1 / 2}} \tag{3.19a}
\end{equation*}
$$

ard

$$
\begin{equation*}
\cosh \omega=-1+\frac{2\left(2 / m_{e} E-q_{2}^{2}\right) \Delta q^{2}}{\left(p_{p}^{2}+q_{k}^{2}\right)^{2}} \tag{3.19b}
\end{equation*}
$$

It is apparent that $T_{C}$ is independent of the angular part of the vector $q_{2}$. The ground state hydrogen atom wave functions $\phi_{15}\left(q_{2}\right)$ in (3.11). are also independent of angle, so the integration over angle car be performed trivially. The momentum representation of the functions
$\phi_{S}(q)$ is given by (Bethe and Salpeter, p.125)

$$
\begin{equation*}
\phi_{15}(q)=\frac{2 \sqrt{2}}{\pi} \frac{p_{0}^{5 / 2}}{\left(p_{0}^{2}+q^{2}\right)^{2}} \tag{3.20}
\end{equation*}
$$

Expressing all quantities in atomic units, that is, momenta in units of the Bohr momentum $p_{0}$, and energies in Rydbergs, then we obtain for $\langle f| T_{2}^{c}(E)|i\rangle$

$$
\langle F| T_{2}^{c}(E)|i\rangle=\frac{32}{\pi^{2} m_{e} \Delta q} \int_{0}^{(E)^{4_{2}}} \frac{d g}{\left(1+q^{2}\right)^{5}\left(1+\frac{q^{2}}{2} z\right)^{4^{2}}(1-\exp (-2 \pi v))}(3.21)
$$

where

$$
\begin{equation*}
z=\frac{2\left(E-q^{2}\right) \Delta q^{2}}{\left(1+q^{2}\right)^{2}} \tag{3.22a}
\end{equation*}
$$

and

$$
\begin{equation*}
\cosh \omega=1+z \tag{3.22b}
\end{equation*}
$$

$$
\begin{equation*}
\nu=\frac{1}{\left(E-q^{2}\right)^{1 / 2}} \tag{3.22c}
\end{equation*}
$$

## b) the electron-electior term $\langle F| T_{3}^{\text {( }}(E)|i\rangle$

We can see from Equations (3.2), (3.6) and (3.12) that

$$
\begin{align*}
T-\varepsilon & =\frac{q_{12^{2}}}{2 \mu_{12}}-\left(\frac{q F^{2}}{2 \mu_{1}}-\frac{p_{0}}{2 u_{23}}-\frac{q_{3}^{2}}{2 u_{3}}\right)  \tag{3.24}\\
& =\frac{1}{2 m_{3} \rightarrow \infty}\left(q_{23^{2}}+p_{0}^{2}\right)>0
\end{align*}
$$

We car similarly show that $\left(T^{\prime}-\varepsilon\right)>0$ and hence from Equation (2.42) for the repulsive interaction, we must choose $B\left(T, T^{\prime}\right)=\exp (-2 \pi 0)$. The sign of $(T-\varepsilon)$ and ( $T^{\prime}-\varepsilon$ ) implies that the electron-electror paths are solely in the classically inaccessible region of momentum space.

Again expressing all quantities in atomic units we obtain from Equations $(2.12)$ and $(3.24)$ the expression for $T_{c}$
where

$$
\begin{gather*}
T_{c}=\frac{p_{0}^{3} \exp (-i v \omega) \exp (-2 \pi v)}{2 \pi m_{e} \Delta q\left(1+q_{23}^{2}\right)^{1 / 2}\left(1+q_{2} 3^{2}\right)^{1 / 2}\left(1+\frac{1}{2} z\right)^{1 / 2}} \frac{1}{1-\exp (-2 v v)}(3.25) \\
z=\frac{2\left(2 E-q_{2}{ }^{2}\right) \Delta q^{2}}{\left(1+q_{23}^{2}\right)\left(1+q_{23}^{12}\right)}  \tag{3.26a}\\
\cosh \omega=1+z \tag{3.26b}
\end{gather*}
$$

and the coordinate relations are

$$
\begin{align*}
& q_{23}=q_{3}+q_{5}  \tag{3.27a}\\
& q_{23}^{\prime}=q_{3}+q_{3} \tag{3.27b}
\end{align*}
$$

We see from these relations that the electron-electron $T$ matrix is dependent on $\hat{q}_{3}$, and this makes this contribution more difficult to evaluate than the one from the electron-proton interaction. On substitution

$$
\begin{align*}
& \text { of equations (3.20) and (3.25) into (3.14) we obtain } \\
& \left.\qquad F\left|T_{3}^{c}(E)\right| i\right\rangle \\
& =\frac{4}{\pi^{3} m_{e} \Delta q} \int_{\left.0<l_{23} 1<22^{2}\right)^{4} 2^{2}} \frac{\exp (-i \nu \omega) \exp (-2 \pi v)}{\left(1+q_{23}^{\prime 2}\right)\left(1+\frac{1}{2} z\right)^{1 / 2}(1-\exp (2 m v))} \\
& \qquad v=\frac{2}{\left(2 E-q_{3}^{2}\right)^{1 / 2}}
\end{align*}
$$

From Equations (3.27) and (3.29) we see that we need to know the angles between $q_{3}$ and $q_{F}$, and between $q_{3}$ and $q_{i}$. Ne are at liberty to choose the orientations of $q_{i}$ and $q_{f}$ in momentum space. For convenience we have chosen the polar axis to bisect the scattering angle $\theta$ so that $q$. and $q$. are coplanar and are aligned as shown in Figure (3.3). Then the angles between the two fixed vectors and $q_{3}$, which has polar angles $\theta$ and $\phi$, are given by

$$
\begin{align*}
& \cos \left(q_{3}, q_{i}\right)=-\sin \theta-\sin \phi \sin \theta / 2+\cos \theta \cos \theta / 2 \quad \text { (3.29a) } \\
& \left.\cos \left(q_{3}, q_{F}\right)=\sin \theta \sin \phi \sin \theta / 2+\cos \theta \cos \theta / 2 \quad \quad \quad 3.29 b\right)
\end{align*}
$$

Writing Equation (3.28) more explicitly we now obtain $\langle F| T_{3}^{2}(E)|i\rangle$

$$
=\frac{4}{\pi^{3} m_{e} \Delta q} \int_{0}^{2 \pi} d \phi \int_{0}^{\pi} d \theta \sin \theta \int_{0}^{(2 E)^{2 / 2}} \frac{d q_{3} q_{3}^{2} \exp (-i v \omega) \exp (-2 \pi v)(3.30)}{\left(1+q_{23}^{2}\right)^{5 / 2}\left(1+q_{23}^{12}\right)^{5 / 2}\left(1+\frac{1}{2} z\right)^{1 / 2}(1-\exp (-2 \pi v))}
$$

where

$$
q_{23}^{2}=q_{f^{2}}+q_{3}^{2}+2 q_{3} q_{F}=\cos \left(q_{3}, q_{F}\right)
$$

and

$$
\begin{equation*}
q_{23^{\prime 2}}=q_{i}{ }^{2}+q_{3}{ }^{2}+2 q_{3} q_{i} \cos \left(q_{3}, q_{i}\right) \tag{3.316}
\end{equation*}
$$

FIGURE 3.3

The orientation of the vectors $q_{i}, q_{F}$ and $q_{s}$.
qi has polar coordinates $(q i, 2 \pi-\theta / 2,0)$.
$q_{E}$ has polar coordinates ( $q, \theta / 2,0$ ).
$q$ has polar coordinates $\left(q_{3}, \alpha, \phi\right)$.

FIGURE 33

Finally we express the results for the electron-proton and electron-electror interactions in terms of their contributions to the scattering amplitude $F(E, \theta)$. From Equations (3.2), (3.23) ant (3.23), and writing $F_{2}^{c}(E, \theta)$ for the contribution to the scattering amplitude from the elcctror-proton classical path. term, we obtain

$$
\begin{equation*}
F_{2}^{C}(E, \theta)=\frac{128}{\Delta q} \int_{0}^{(E)^{4 / 2}} \frac{d q q^{2} \exp (i v \omega)}{\left(1+q^{2}\right)^{5}\left(1+\frac{1}{2} z\right)^{1 / 2}(1-\exp (-2 \pi v))} \tag{3.32}
\end{equation*}
$$

and

$$
F_{3}^{c}\left(E_{1} \theta\right)=\frac{-16}{\pi \Delta q} \int_{0<i q v i<(E)^{1 / 2}} d q_{3} \frac{\exp (-i v \omega) \exp (-2 \pi v)}{\left(1+q_{23}\right)^{5 / 2}\left(1+q 23^{12}\right)^{5 / 2}\left(1+\frac{1}{2} z\right)^{1 / 2}(1-\exp (-2 \pi v))}
$$

### 3.4 Evaluation of the Born Term $\langle F| T^{0}(E)|i\rangle$

From Equations (2.35a), (2.42a), (3.11) and (3.14) it is apparent that the two-body $T$ matrix, $T_{B}$, for both elєこtron-proton and electron-slectron interactions is independent of the variables of integration. The contribution to the scattering matrix then reduces in both cases to integrating a product of bound state hydrogen atom wave functions.

For the electron-proton case we have

$$
\langle F| T_{2}^{B}(E)|L\rangle=\frac{-p_{c}^{c}}{2 \pi^{2} \mu_{13} \Delta q^{2}} \int d q \phi_{15}^{*}(q) \phi_{15}(q)(3.34)
$$

Ne have argued, (Equation 3.15), that the limits on the integration over $|q|$ should be $0<|q|<(E)^{1 / 2}$. The integrand in (3.34) is proportional to $q^{-6}$, so in fact for all but the lowest energies, contributions from the region $(E)^{1 / 2}<|q|<\infty \quad$ will be insignificant.

However by extending the upper limit of integration to infinity in Equation (3.34) we are able to perform the integration analytically without changing the result. We obtain

$$
\begin{equation*}
f_{2}^{B}(E, \theta)=\frac{2}{\Delta q^{2}} \tag{3.35}
\end{equation*}
$$

where $F_{2}{ }^{8}\left(E_{1}, \theta\right)$ is the contribution to the scattering amplitude from the electron-proton Born term of the $T$ matrix.

This is exactly the same result as a standard first Born calculation of the contribution to the scattering amplitude from the electron-proton interaction.

The Born term of the $T$ matrix for the electron-electron interaction gives the following contribution to the scattering matrix
 Using the same arguments as in the previous calculation we can extend the limits of the integration to all $\left|q_{3}\right|$ space, and though the integral is slightly more difficult than in the previous case, it can be evaluated analytically (see Appendix) to give

$$
\begin{equation*}
f_{3}^{B}(E, \theta)=\frac{-32}{\Delta q^{2}\left(\Delta q^{2}+4\right)^{2}} \tag{3.37}
\end{equation*}
$$

This again is the same result as that given by the first Born approximation. Thus, using the derived
form of the two -body off-shell Coulomb' $T$ matrix in the first order iterate of the Faddeev equations demonstrates expl:aitly that the latter contain tine first Bors approximation for the elastic e-H scattering problem.

Summing Equations (3.35) and (3.37) we obtain the total contribution to the scattering matrix from the Born term of the two-body $T$ matrix.

$$
\begin{equation*}
F_{B}(E, \theta)=\frac{2\left(\Delta q^{2}+8\right)}{\left(\Delta q^{2}+4\right)^{2}} \tag{3.38}
\end{equation*}
$$

### 3.5 Evaluation. of the pole terms

From the expressions for the two-body off-shell Coulomb $T$ matrix we see that the pole term is in fact an infinite sum of contributions. On the energy shell only the $n=0$ term contributes, so we shall initially calculate this term.

We already know, from our calculations of the classical path contributions, the sign of the factors $(\varepsilon-T)$ and $\left(\varepsilon-T^{\prime}\right)$, so we can infer that for both attractive and repulsive interactions the factor $\quad \xi=\operatorname{sign}(\varepsilon-T)\left(\varepsilon-T^{\prime}\right)$ is positive . In fact it is apparent from Equations (2.35b) and (2.42b) that the pole terms for the attractive and repulsive interactions differ only by sign and mass factors.

## a) the elactron-oroton term $\langle f| T_{2}^{p}(E)|i\rangle$

The analysis is much the same as for the classical
$p=$ th term and we shall just quote the result for $\langle F| T_{2}^{P(0)}(E)|i\rangle$, the zero order pole term for the electron-proton interaction

$$
\langle F| T_{2}^{P_{0}()}(E)|i\rangle=\frac{16}{\pi^{3} m_{e} \Delta q} \int_{0}^{(E)^{1 / 2}} \frac{d q q^{2}\left(E-q^{2}\right)^{1 / 2}}{\left(q^{2}+1\right)^{5}(1+1 / 2 z)^{1 / 2}} \quad \text { (3.37) }
$$

where $z$ is defined by (3.22a). The analysis is simply extended to include all orders of the pole term. We note from Equation (2.35b) that for $\xi_{\mathcal{L}}=1$, the contribution from $n=-1$ is equal to the contribution from $n=1$. Thus, the $n$th order pole term (where $n$ can be positive or negative) is given by

$$
\langle F| T_{2}^{(n)}(E)|i\rangle
$$

$$
=\frac{16}{\pi^{3} m e \Delta q} \int_{0}^{(E))^{1 / 2}} \frac{d q q^{2}\left(E-q^{2}\right)^{1 / 2}}{\left(q^{2}+1\right)^{5}\left(1+\frac{1}{2} z\right)^{1 / 2}\left[n^{2}\left(E-q^{2}\right)+1\right]\left[1+z+(z(z+2))^{1 / 2}\right]^{n 1}}
$$

## b) the eleciron-electron term $\langle F| T_{3}{ }^{\prime}(E)|i\rangle$

Actin this calculation is more difficult than the ore for the electron-proton contribution, however utilising the results of the classical path electron-electron calculation we may write down the analogues of equations (3.39) and (3.40)

$$
\langle f| T_{3}^{(0)}(E)|i\rangle
$$

$$
\begin{align*}
& \Gamma_{3}^{r(0)}(E)|i\rangle  \tag{3.41}\\
& =\frac{-1}{\pi^{4} m_{e} \Delta q} \int d q_{3} \frac{\left(2 E-q_{3} 3^{3 / 2}\right.}{\left(1+q q_{2}^{2}\right)^{1 / 2 / 2}\left(1+q_{23} 3^{2}\right)^{1 / 2}(1+1 / 2 z)^{1 / 2}} \quad(3.41)
\end{align*}
$$

where $q_{23^{2}}{ }^{2} q_{23^{12}}$ and $z$ are defined by (3.31a), (3.31b) and ( $3.2 \epsilon a$ ) respectively.

$$
\begin{align*}
& \langle f| T_{3}^{p(n)}(E)|i\rangle \\
& \begin{array}{l}
=\frac{-4}{\pi^{4} m_{e} A_{q}} \int d q_{3} \frac{\left(2 E-q_{2}\right)^{1 / 2}}{\left.\left(1+q_{2}\right)^{2}\right)^{3 / 2}\left(1+q_{2} 3^{2}\right)^{5 / 2}\left(1+t^{1 / 2}\right)^{1 / 2}\left[n^{2}\left(2 E-q^{2}\right)+4\right]} \\
\end{array} \quad \begin{array}{l}
\frac{1}{\left[1+z+(z(z+2))^{1 / 2}\right]^{n+1}}
\end{array} \tag{3.42}
\end{align*}
$$

We therefore obtain for the contribution. 3 to the scattering amplitude from the nth order pole terms $F_{2}^{p(n)}\left(E_{1} \Theta\right)$

$$
=\frac{-64}{\pi \Delta q} \int_{0}^{(E)^{1 / 2}} \frac{d q q^{2}\left(E-q^{2}\right)^{1 / 2}}{\left(1+q^{2}\right)^{5}\left(1+\frac{1}{2} z\right)^{1 / 2}\left[n^{2}\left(E-q^{2}\right)+1\right]\left[1+z+\left(z(z+2)^{1 / 2}\right]^{n / 2}\right.}(\cdot 43)
$$

and
$F_{3}^{e(n)}\left(E_{1} \theta\right)$

$$
=\frac{16}{\pi^{2} \Delta q} \int d q_{3}-\frac{\left(2 E-q_{3}^{2}\right)^{1 / 2}}{\left(1+q_{23}\right)^{5} 2^{1 / 2}\left(1+q_{2} 3^{2}\right)^{5 / 2}(1+1 / 2 z)^{1 / 2}\left[n^{2}\left(2 E-q^{2}\right)+4\right]} \times \sqrt{\left.z+1+(z(z+2))^{2 / 2}\right]^{1}}
$$

Before quoting the results for the calculations of

$$
F^{B}(E, \theta), F^{P}(E, \theta) \text { and } F^{C}(E, \theta) \text {, we note that the }
$$ pole terms and Born terms arc purely real, whilst the classical path term, has a complex part. Thus the complex part of the scattering amplitude is contained solely from contributions from the classical path terms. Ne obtain the total contribution for each of the three terms by summing the contributions from the electron-proton and electron-electron interactions, the real and imaginary parts being summed separately for the classical path term.

### 3.5 Calculations and Results

The Born contribution to the scattering amplitude has been evaluated analytically. Unless we make further approximations the pole terms and the classical path term must be evaluated numerically. For both of these terms the electronproton contribution is a one-dimensional integral whilst the electron-elestron contribution involves a more difficult three-dimensi=nal integration. We shall firstly evaluate the various orders of the pole term and compare
the coniributions to the scatterine amplitude with those obtained from the Born term. ile may therefore examire whether the on-shell corsespondence identity is being approacinec.
2) The Pal. and Bymn terms

On examiration of the integrands of Equations (3.39) (3.11) at hich energies it is apparent that tre majority of the contributions to the integrals come from small $q$ or $\left|q_{3}\right|$. This would indicate that the on-shell limit is teine approashed since for example, this limit is given for the electron-proton interaction by

$$
\frac{q_{31}^{2}}{2 u_{31}} \sim \frac{q F^{2}}{2 m_{e}} \rightarrow \frac{q c^{2}}{2 m e}-\frac{q_{0}^{2}}{2 m e}-\frac{q^{2}}{2 u_{2}}
$$

At high energies $q F^{2} \gg p_{0}{ }^{2}$, and hence the on-shell limit is approached when $q$ is small. A similar argument holis for the electron-electron interaction.

The integrations in Equations (3.39) and (3.40) are performed using a subroutine aKaEf4 of Banks. One half a second of processing time is taken on the Elliott 4130 at Stirling to provide a result for the scatterir.g amplitude at one energy and one angle. The electron-electron interaction integrals are performed by using the RKMER 4 routine twice and a Gaussian method for the $\phi$ integration, the integrands being a slowly varyine function of the azimuthal angle. The time to achieve one result is much lonser, being of the order of one and a half minutes.

In Figures (3.4) and (3.5) we compare the contributions to the scattering amplitude from the $n=0$ pole term with that from the $n= \pm 1$ pole terms at energies of 200 e and 1 kev , and at scattering angles between $5^{\circ}$ and $90^{\circ}$. At 200 vv and $5^{\circ}$ scattering angle the contribution from the first order terms is approximately $1 \%$ of the contribution from the zeroth order pole term, this percentage decreasing rapidly with increasing angle. For scattering at lev the value of the contributions from the $n= \pm 1$ terms relative to those from the $n=0$ term is even less thar. the 200 ev case at all angles of scattering. Thus for energies greater than 200 ev , contributions from, the First order pole term are negligible in comparison with the zeroth order contribution, an effect which increases with increasing energy. This effect is evidence that the on-shell limit is being approached at high energies. By examination of Equations (3.40) and (3.42) it is evident that contributions from the $n= \pm 2$ pole terms will be less than those from the $n= \pm 1$ terms. We shall therefore neglect all but the zeroth order pole term in our calculations.

In Figures (3.6) and (3.7) we compare the contributions to the scattering amplitude from the zero order pole term with those from the Born term. At an energy of 200ev for scattering angles below $30^{\circ}$ there is no evidence of cancellation of the Born and pole contributions. However at scattering aneles above $30^{\circ}$ the percentage difference between the magnitudes of $F^{B}(E, \theta)$ and $F^{P}(E, \theta)$

FIGURE 3.7

is never greater than $20 \%$ reducing rapidly as the arfle increases so that the contributions almost cancel at $90^{\circ}$ scatterine ancle. At lkev this persentage differen=e is smaller than that at 200 ev for all scatterins argle3. Henceforth we shall ignore contribu:ions from the pole and Born terms for $E \geqslant 200 \mathrm{eV}$ and $\theta \geqslant 30^{\circ}$, an approximation which is very food for a large part of thisrange and still good for lower energies and ancles. The carcellation of the pole and Born contributions is a further indication that the on-shell limit is approached at hiph energies.

Thus, for the anglé and energy range defined, we can to a good approximation express the scattering amplitude, and therefore the differential cross section, in terms of the classical path part of the $T$ matrix. The on-shell correspondence identity is being satisfied and a physical explanation of this phenomena can be obtained from consideration of a classical picture of the collision process as follows.

At high erergies the electron velocity is large and the time of interaction between the electron and the atom is short compared with the period of rotation of the bound electron around the nucleus.. We can assume that for large angles of scattering the electron has passed close to the nucleus, (i.e. the impact parameter is small), and the effect of the bound electron is small. In fact the
effect of the bound electron is a small perturbation of the two-body Rutherford scatterine process and a co-respondence identity is known to exist for the latter (Norcliffe et.al., 1969b). For low ancles of scattering the impact parameter is large, contributions from the electron-electron interaction become important, and the Rutherford scattering identity no longer holds. The electron-electron interation is also important at low energies when the period of the bound electron is much shorter than the interaction time. Therefore, in the region of scattering we have defined, which is close to the on-shell region for elastic e-H collisions, the Rutherford correspondence identity is approached and the scattering amplitude can be expressed in terms of classical paths. For lower energies and angles of scattering, quantal and three-body effects are important (viz. the pole and Born terms) and the scattering amplitude cannot be expressed so simply.
b) The Classical Path Term

The computational procedure for calculating the classical path terms is similar to that used to obtain the pole terms. Again the electron-proton sirgle integral given by equation (3.32) can be evaluated relatively simply and quickly, whilst the electron-electron contribution proves more difficult to compute. Both terms contribute real and complex parts to the scattering amplitude. The angular distributions of the contributions are shown for two-energies in Figures (3.8) and (3.9).

Integer in parenthesis indicates appropiarte power of 10 .

FIGURE 3.9

Contributions to the scattering amplitude in atomic units from the classical path term at incident energy $E=1 \mathrm{kev}$.
integer in parenthesis indicates appropiarte power of 10 .

For scattering anclis above $30^{\circ}$ the contributions from the electron-electron interaction are neglifible. This is in accordance with the areuments in the last paragraph of Sectior 3.6a. In later calculations it shall be convenient to neqlect the electron-electron contributions, thouzh we revain them for completeness in this section.

The differential cross section is found by taking the modulus square of the scattering amplitude. Our results for $d / / d u$ for elastic e-H scatterire are shown by curve 1 of Figures (3.10) and (3.11), where a comparison is made with the results obtained using a standard first Born approximation calculation.

At $E=200 \mathrm{ev}$ the discrepancy between the Born result and the classical path result is large. For scattering angles less than $30^{\circ}$ the Born differential cross section approaches a constant at zero angle, whereas the classical path result peaks sharply. In fact, as we shall see, the classical path differential cross section is divergent at zero angle scattering. Above $30^{\circ}$ scattering angle although the angular distributions predicted by the two theories are similar, the classical path differential cross section is considerably larger than the Born. At lkev scattering the angular distributions are similar to those at 200 ev , however for large angle scattering the magnitude of the Born and the classical path results are closer though by no means equal.

## FIGURE 3.10

The angular distribution of the differential cross section for the collision $e^{-}+H(1 s) \rightarrow e^{-}+H(15)$ ar incident energy 200 ev .

## Figure 3.11

The angular distribution of the differential cross section for the collision $e^{-}+H(1 s) \rightarrow e^{-}+H(s)$ at incident energy 1 kev .

At energies higher than lkev we can show both rumerically and analytically that the classical path differential cross section approaches the Born for all but small anfles. However, at 1500 ev the classical path approximation differs from the Born by $40 \%$ (Hutton and Roberts, 1972) and one must go to very high energies before the results agree.

Chen et.al. (1972) have evaluated the angular distribution for the elastic e-H scattering process using the firstorder iterate of the Faddeev equations ard a form of the two-body off-shell Coulomo $T$ matrix derived from the Schwinger contour íntegral represertation (Chen and Chen, 1972). The latter is equivalent to the Roberts form but Chen essentially calculates the differential cross section retaining all three parts of the $T$ matrix. At 200 ev above ancles of $30^{\circ}$ Chen's results are indistinguishable from ours. This confirms the supposition that in this scattering range one can predict differential cross sections correctly in the Faddeev approximation by retaining only the classical path term in the expression for the $T$ matrix. Below $30^{\circ}$ scattering anglechen's results differ only slightly from ours and appear to diverge at zero angles of scattering.

Chen compares his results with the relative experimental measurements of Teubner et.al. (unpublished) and a Glauber approximation result (Tai et.al., 1969). The angular distribution agrees with the experimental findings over much of the range, but of course the same
aereement is found between the Born calculation and the renormalized experimental results. A lack of absolute experimental measurements at 200 ev make it impossible to verify conclusively the masnitude of the differential cross sectior, though recent absolute measurements for 50ev e-H elastic scattering (Teubrer et.al., 1973) seem to suggest that the Born approximation gives the more accurate prediction. Above $30^{\circ}$ scattering the Born and Glauber results are identical. Recent work by Chen (Chen et.al., 1973) shows that in the second order iterate of the Faddeev equations for elastic e-H scattering, the differential cross section reduces to the Glauber result.

In Figure (3.12) we present a distribution of the differential cross section as a function of energy at a fixed scattering angle. Choosing $\theta=60^{\circ}$ we can ignore contributions from the electron-electron interaction so that the differential cross section is calculated from the classical path electron-proton part of the $T$ matrix only. The energy dependence of the differential cross section calculated from the classical path approximation is seen to be similar to the Born distribution, and in the high energy limit there is a slow convergence of the former result on the latter. From our results and Chen's we conclude that only for very high energies do differential cross sections calculated from the first order Faddeev equations tend to the first Born approximation result.

## c) Zero arne calculations

As the scattering angle approaches zero we can approximate several of the factors in the classical path terms, which maksthe latter easier to compute and gives insight into the source of the zero angle divergence of the differential cross section. From Equations (3.21) and (3.22a,b) for the electron-proton classical path term we see that as
$\theta \rightarrow 0$ then $z \rightarrow 0$ and using the logarithmic representation of $\omega$,

$$
\omega=\log _{1 / 2}\left[1+z+(z(z+2))^{1 / 2}\right]
$$

we see that $\omega \rightarrow(2 z)^{1 / 2}$ in this limit. Utilising this result we obtain the following expressions for the real part $f_{2}^{C R}(E, \theta)$ and the imaginary part $F_{2}^{C I}(E, \theta)$ of the scattering amplitude

$$
\begin{aligned}
& f_{2}^{C R}(E, \theta)=\frac{128}{\Delta \rightarrow 0} \int_{0}^{E^{1 / 2}} \frac{d q q^{2}}{\left(1+q^{2}\right)^{5}(1-\exp (-2 \pi 0))}(3.47 a) \\
& f_{2}^{C R}(E, \theta)=256 \int_{0}^{E^{1 / 2}} \frac{d q q^{2}}{\left(1+q^{2}\right)^{2}(1-\exp (-2 \pi \nu))}
\end{aligned}
$$

and

For the electron-electron term we can perform two of the three integrations analytically in the $\theta \rightarrow 0$ limit and we obtain the result from Equation (3.30)

$$
\begin{aligned}
& F_{3}^{c R}\left(E_{1} \theta\right) \\
&\left.=\frac{4}{q_{i} \Delta q} \int_{0}^{(2 E)^{1 / 2}} \frac{q d q}{(\exp (2 \pi v)-1)}\left[\frac{1}{\left\{1+\left(q+q_{i}\right)^{2}\right\}^{4}}-\frac{1}{\left\{1+(q-q i)^{2}\right\}^{4}}\right] 3.49 a\right) \\
& f_{3}^{c=}\left(E_{1} \theta\right) \\
&=\frac{12.8}{q_{i}} \int_{0}^{(2 E)^{1 / 2}} \frac{q d q}{(\exp (2 \pi v)-1)}\left[\frac{1}{\left\{1+(q-q i)^{2}\right\}^{5}}-\frac{1}{\left\{1+(q+q i)^{2}\right\}^{5}}\right]
\end{aligned}
$$

From thess results we see that in both cases the real part of the scattering amplitude diverges as $(\Delta q)^{-1},\left(\Delta_{q}=2 q ; \sin \theta / 2\right.$ for clastic collisions), whereas the imaginary part is finite at zero argles. Numerical calculations on the above results give the same values for the zero angle differential cross section as calculations performed at small scattering aries $(\sim 0.10)$ using the general form of the classical path term. This is a valuable check on the correctness of our computational procedure. It is also of rote that $f_{3}^{C R}(E, \theta)$ and $F_{2}^{C R}(E, \theta)$ are of opposite sign at small angles which leaves the possibility that the zero angle divergences in the scattering amplitude may cancel.

We have mentioned that we do not expect the classical path term to provide good results at small angles of scattering. It is more interesting to examine the behaviour of the contributions from the full $T$ matrix, including the $\varepsilon<0 T$ matrix, at zero angles. Taking the zero angle limit $\omega \rightarrow 0$ of the factor representing the sum of the pole and classical path terms we obtain

$$
\begin{aligned}
& {\left[1 / 2 \sum_{n=-\infty}^{\infty} \frac{e^{-|n| \omega}}{n^{2}+v^{2}}-\frac{\pi \exp (i v \omega)}{\sqrt{(1-\exp (-2 \pi v))})] \underset{\Theta \rightarrow 0}{ }-\frac{\pi}{2 j}} \begin{array}{l}
\text { (3.50) } \\
\text { In the same way } \chi \rightarrow 0 \text { in the zero angle limit and we }
\end{array} .\right.}
\end{aligned}
$$ obtain for $\langle f| T_{2}(E)|i\rangle$ a sum of three terms $\langle f| T_{2}(E)|i\rangle \underset{\theta \rightarrow 0}{\overline{=}}\langle F| T_{2}^{B 0}|i\rangle$

$$
\begin{equation*}
+\frac{p_{0}^{2}}{2 \pi m e \Delta q}\left[\int_{E^{1 / 2} \psi|q| \ll} \frac{d^{3} q|\phi(q)|^{2}}{\left(1+q^{2}\right)}-\int_{0<|q|<E^{2} q^{2}} \frac{d^{3} q|\phi(q)|^{2}}{1+}\right] \tag{3.51}
\end{equation*}
$$

where $\langle F| T_{2}{ }^{80}|i\rangle$ is the Born term at zero scattering angle, and the second and third terms come from the
$\varepsilon<0, \varepsilon>0 T$ matrix respectively. For the electronelectron interaction we have in the zero angle limit $\langle F| T_{3}(E)|i\rangle=\langle F| T_{3}{ }^{\circledR}|i\rangle$ $\frac{-p_{0}^{2}}{2 \pi m_{e} \Delta q}\left[\int_{(2 E)^{1 / 2} \leqslant \mid q k q_{0}^{2}} \frac{d^{3} q|\phi(c)|^{2}}{1+q^{2}}+\int_{0<|q|<e^{2}} \frac{d^{3} q|\phi(q)|^{2}}{1+q^{2}}\right]$ (3.52) Since $\langle f| T_{3}^{\infty}|i\rangle+\langle f| T_{2}^{\infty}|i\rangle$ is finite in the zero angle limit then the three-body $T$ matrix is given by

$$
\begin{equation*}
\langle F| T(E)|i\rangle=\text { conot }-\frac{p_{0}^{2}}{\pi m_{2} \Delta_{q}} \int_{\alpha|q|<E^{1 / 2}} \frac{d^{3} q|\phi(q)|^{2}}{1+q^{2}} \tag{3.53}
\end{equation*}
$$

Therefore the scattering amplitude diverges as
$(\Delta q)^{-1}$ at zero scattering angles. In physical reality this of course is not true, and it appears that the zero angle divergence of the differential cross section for elastic scattering is inherent in the Faddeev approximation because of the long range nature of the Coulomb potential. Chen and Sinfailam (1972) also obtain a zero angle divergence for elastic epH scattering, although they have not included the effect of the $\varepsilon<0 T$ matrix, and attribute this to the same cause (Chen, private communication).

We note from Equations (3.51) and (3.52) that a change of sign in one term would cause the cancellation of the $(\Delta q)^{-1}$ divergence. In a previous note (Hutton and Roberts, 1972, heareafter referred to as Paper II),
it was stated that by altering the $g\left(T_{1} T^{\prime}\right)$ factor in Equation (2.35c) for the electron-proton interaction, cancellation of the $(\Delta)^{-1}$ sincularity could be obtained. This is inconsistent and incorrect. The
$3\left(T_{1} T^{\prime}\right)$ factors are uniquely defined in the formalism and even if the reasons given for chaneing 3 (T, T' (viz. that the value of the factor $\eta\left(T_{1} T^{\prime}\right)$ depends on the normalisation of the Coulomb disiorted spherical wave associated with $\tilde{G}_{0}^{(t)}$, see Chapter 2 page 30 ) were valid, then to be consistent $g\left(T, T^{\prime}\right)$ would have to be changed for the repulsive irteraction so that the divergence would not be cancelled.

In Paper II we presented results for the differential cross section cbtained by taking different $3\left(T, T^{\prime}\right)$ factors in Equation (3.32). We demonstrated that the magnitude of the differential cross section is strongly dependent on which value of $g\left(T, T^{\prime}\right)$ is used, apart from in the high energy limit when all three factors give results which converge on the Born. Re-examination of the derivation of the $g\left(T_{1} T^{\prime}\right)$ factors has confirmed that the value used in Equation (3.32) is correct and that the results presented in Fipure (3.9) are the true value of the differential cross section obtained from,the first order iterate of the Faddeev equations for the process considered. The discrepancy between the magnitudes of the differential cross sections given in the first order Born and Faddeev methods at large scattering angles is real and due to the
fact that important contributions are contained in the second order Faddeev term (Chen et.al., 1973). The zero angle divergence of the differential cross section is a ron-physical property associated with the lone range nature of the Coulomb potential.
c) High energy limit

At high energies ( $E$ フalkev) and scattering angles above $10^{\circ}$ the electron-electron classical path contribution is small and we can express the scattering amplitude solely in terms of the electron-proton contributions. In the high energy limit we know that the major contribution to the integral in Equation (3.32) comes from small $q$ and we may write

$$
f_{2}^{c}(E, \theta)=\frac{64}{\pi \Delta \Delta^{2}} \int_{0}^{\infty} \frac{d q q^{2}}{\left(1+q^{2}\right)^{4}} \exp (i v \omega) \text { (3.54) }
$$ In the high energy limit $v \omega$ is independent of $q$ and may be written

$$
\begin{equation*}
\nu \omega=E_{E \rightarrow \infty}=-1 / 2 \log \left(1+2 E \Delta q^{2}\right) \tag{3.55}
\end{equation*}
$$

Thus $V W$ approaches zero slowly in the limit $E \rightarrow \infty$ for nonzero scattering angles, and in this limit the scattering amplitude reduces to a real function which is equal to the first Born result.

$$
\begin{equation*}
f_{2}^{c}(E, \theta) \underset{E \rightarrow \infty}{=} \frac{2}{\Delta q^{2}}=f_{2}^{B}(E, \theta) \tag{3.56}
\end{equation*}
$$

According to Norcliffe et.al. (1960) Vt is the classical action function in units of $\hbar$ alone, in this case, a path joining the vectors $q_{i}$ and $q_{f}$. We can assume then that the classical action must approach zero in the high energy limit. From Equation (2.38) we see that the action along the path between the fixed vectors $q_{i}$ and $q_{f}, S_{f i} \approx r_{0} \Delta q$ where $r_{0}$ is the distance of closest approach. It is a well known result of classical mechanics that for hyperbolic orbits the distance of closest approach $r_{0} \propto q^{-2}$. Therefore the action $S_{F_{1}}$ is proportional to $q_{i}^{-1}$ and at high energies and fixed scattering angles $S_{f i}$ tends to zero. We infer that the slow convergence of the first order Faddeev result on the Born, is in part associated with the action along the classical paths slowly approaching zero in the high energy limit. We assume that the second order Faddeev calculations of Chen et.al. (1973) will bear some relationship to this phenomena.

### 3.7 The Total Cons Section

The total cross section for elastic scattering is given by

$$
\begin{equation*}
\sigma=2 \pi \int_{0}^{\pi}|f(E, \theta)|^{2} \sin \theta d \theta \tag{3.57}
\end{equation*}
$$

We shall investigate the use of the classical path
expression for the scattering amplitude in Equation (3.57). An obvious difficulty arises at small scattering angles as $\left|f^{c}(E, \theta)\right|^{2}$ is singular at $\theta=0$. In Figure (3.13) we have plotted the integrand $\left|f\left(E_{1} \theta\right)\right|^{2} \sin \theta$ as a function of the scattering angle $\theta$ for both the Born and the classical path approximations at $E=1 k e v$. Clearly

## FIGURE 3.13

there is a massive discrepancy at small aneles. The Born result for $\sigma$ is generally believed to be good because of the small angle behaviour of the differential cross section in the Born approximation. Therefore using the classical path approximation $F^{C}(E, E)$ in Equation (3.57) will lead to total cross sections which are orders of marnitude too large.

We have attempted to over come this difficulty by introducing a cut-off in $f^{c}(E, \theta)$ at a certain
$\theta$, and extrapolating to small $\theta$ using an expansion of $F^{C}(E, \theta)$ about $f^{c}(E, O)$. However, the choice of the cut-off. angle and the type of expansion used are so arbitrary that the results for $\sigma$ are meaningless. In no circumstances were we able to reproduce the correct high energy behaviour of $\sigma$, which is $E^{-1}$ as predicted by the Born approximation.

## b) The Optical Theorem

The optical theorem relates the total cross section, $\sigma_{\text {tot }}$, for all processes, elastic, excitation and ionisation from the ground state, to the imaginary part of the forward scattering amplitude (Messiah,p.866)

$$
\begin{equation*}
\sigma_{\text {tot }}=\frac{4 \pi}{q_{i}} \operatorname{lm} F(E, 0) \tag{3.58}
\end{equation*}
$$

In the approximation we have used only the classical path term contains an imaginary part so we can express $\sigma_{\text {rot }}$
in terms of the imaginary part of the zero angle classical path contribution to the scattering amplitude. From Equations (3.43b) and (3.49b) we have
$\sigma_{\text {lot }}=\frac{4 \pi}{q^{2}}\left[256 \int_{0}^{E^{1 / 2}} \frac{d q}{\left(1+q^{2}\right)^{6}} \frac{q^{2}}{(1-\operatorname{expp}(-2 \pi q))}\right)$

$$
\left.+\frac{12.8}{q_{i}} \int_{0}^{(2 E)^{1 / 2}} \frac{q d q}{\left(\exp \left(2 \pi v_{2}\right)-1\right)}\left\{\frac{1}{\left[1+\left(q-q_{i}\right)^{2}\right]^{s}}-\frac{1}{\left[1+\left(q+q_{i}\right)^{2}\right]^{5}}\right\}\right]
$$

where

$$
\begin{align*}
& \nu_{1}=\frac{1}{\sqrt{E}-q^{2}}  \tag{3.60}\\
& v_{2}=\frac{2}{\sqrt{2 E-q^{2}}} \tag{3.60b}
\end{align*}
$$

We are interested in the high energy imit of $\sigma_{\text {for }}$. In this limit $\nu_{1} \rightarrow E^{-1 / 2}$ and the contribution to $\sigma_{01}$ from the electron-proton interaction is given by

$$
\begin{equation*}
\sigma_{t_{0}+}^{(2)}=\frac{4 \pi}{q_{i}} 256 \frac{E^{1 / 2}}{2 \pi} \int_{0}^{\infty} \frac{d q q^{2}}{\left(1+q^{2}\right)^{6}} \tag{3.61a}
\end{equation*}
$$

The integral is obtained trivially and we obtain the high energy limit

$$
\begin{equation*}
\sigma_{\text {tor }}{ }^{(2)} \underset{E \rightarrow \infty}{ } 7 \pi \tag{3.61~b}
\end{equation*}
$$

Similarly the high energy limit of the contribution to the forward angle scattering amplitude from the

$$
\begin{aligned}
& \text { electron-electron paths is } \\
& \begin{aligned}
\sigma_{\text {tot }}{ }^{(3)} & =\frac{4 \pi}{q_{i}} \frac{12.8}{q_{i}} \frac{1}{2 \pi} \frac{E^{4}}{2} \times . \\
& \times \int_{0}^{\infty} q d q\left[\frac{1}{\left\{1+(q-q i)^{2}\right\}^{5}}-\frac{1}{\left\{1+\left(q+q i^{2}\right)\right\}^{5}}\right](3.62 a)
\end{aligned}
\end{aligned}
$$

The integral, although more complicated than that for the electron-proton interaction, can be evaluated by contour
interration and in the high enercy limit gives the result

$$
\begin{equation*}
\sigma_{\text {tot }}^{(3)}=\frac{51 \pi}{2^{7 / 2}} \tag{3.62b}
\end{equation*}
$$

We therefore see that theory predicts that $\sigma_{\text {rot }}$ approaches a constant for $E \rightarrow \infty$. We have checked Equations (3.61b) and (3.62b) numerically, and although at the very high erergies necessary for the asymptotic value to be approached our programme loses accuracy, it appears that the theoretical limits are approached and that $\sigma_{\text {rot }}$ decreases to these values at high energies. The correct behaviour of Gor at asymptotic energies. is given by the Bethe form (Mott and Massey, p.496)

$$
\begin{equation*}
\text { Oror } \overline{\overline{E \geqslant \infty}} E^{-1}(A \log E+B) \pi \tag{3.63}
\end{equation*}
$$

where $A$ and $B$ are constants. Therefore although the first order Faddeev improves on the first order Born, which gives $\sigma_{\text {fol }}=0$ from the optical theorem, it does not give the correct high energy behaviour. In the first order Faddeev approximation three-body effects are neglected and these will alter the behaviour of Orot calculated from the optical theorem, when higher orders of the Faddeev expansion are taken into account. Roberts (1967) has shown that the imaginary part of the forward scattering amplitude calculated in the second Born approximation yields the optical theorem for the first Born approximation. We therefore expect that calculations
of the second order Faddeev amplitude will vastly improve predictions for $\sigma_{\text {tot }}$ got from the optical theorem.

We note that the forward scattering amplitude can be calculated directly from the spectral operator by allowing $f \rightarrow f^{\prime}$ in Equation (2.29). We have a correspondence identity for the spectral operator (Norcliffe et. al., 1969b) and therefore in principle
$\sigma$ +or can be expressed via the optical theorem in terms of classical paths. The subjects of unitarity of the Coulomb $T$ matrix, the spectral operator and the optical theorem are, seen to be interelated to each other and all dependent on classical trajectories.

## CHAPTER 4

## the inelastic e-H scattering problem

In this section we shall deal orly with direct collisions, a brief mention of rearrar.pement collisions will be made in the final chapter. Equations (3.1), (3.2) and (3.4) describing the scattering process, the scattering amplitude ard the conservation of energy respectively, hold for the case of inelastic scattering with minor modifications to some of the terms in the equations. The initial and final energies $E_{i}$ ard $E_{F}$, ard the marritudes of the asymptotic momenta $q_{i}$ ard $q_{f}$ are roo longer equal for inelastic collisions, but must be calculated from Equation (3.4) for each individual process considered. The differential cross section is given in terms of the scattering amplitude by (Mot ard Massey, p.475)

$$
\begin{equation*}
\frac{d \sigma}{d \Omega}=\frac{q^{i}}{\dot{i}}|f(E, \theta)|^{2} \tag{4.1}
\end{equation*}
$$

We shall deal only with the $n=1 \rightarrow 2$ transition in hydrogen. The $n=2$ state of hydrogen has two substates of the orbital quantum number $l ; l=0$ known as the 2 s state and $l=1$, the $2 p$ state. The $2 p$ state is further subdivided into three levels characterised by the magnetic quantum number $m$, which can take the values $0, \pm 1$. Neglecting the spin-crbit and hyperfine interactions the four $n=2$ states are degenerate in
energy, the energy of this level being $E_{2}=-p_{0}^{2} / 8 \mu_{2 s}$. Thus the relationship between the initial ard final momenta is

$$
\begin{equation*}
\frac{q i^{2}-q q^{2}}{2 \mu_{1}}=\frac{3 p_{0}^{2}}{8 \mu_{23}} \tag{4.2}
\end{equation*}
$$

Tree transition amplitude is calculated in the first order iterate of the Faddeev equations for each of the trar.sitions between the ground state and ore of the four excited substates. The total amplitude is just the sum of the individual contributions.

We shall again concentrate our attention or the contributions arising from the classical path tern of the two-body $T$ matrix, and examine the cancellation of the pole ard Bors terms only qualitatively. Much of the analysis follows on from Chapter 3.

### 4.1 The Classical Path. Terms

The coordinate relations in the barycentric frame for the inelastic scattering process are the same as for elastic scattering. Ne car write down the analogues of Equations (3.11) and (3.14) by simply changing the final state wave functions
where $\phi_{2 \ln }(q)$ is the final state wavefurctior. of the bound system.

The definiticr. of the two-body $T$ matrices is dependent or the sign of $(\varepsilon-T)$ and $\left(\varepsilon-T^{\prime}\right)$. For both. the elsctror-pmosor, and the electror-electron interactions we can show that $\boldsymbol{T}_{,} \boldsymbol{T}^{\prime}>\boldsymbol{E}$ as for elastic scattering. We must therefore make the same choices for $B\left(T, T^{\prime}\right)$, that is, $g\left(T_{1} T^{\prime}\right)=1$ for the attractive interaction. arid $g\left(T, T^{\prime}\right)=\exp (-2 \pi \nu)$ for repulsive scattering. Proceeding with the aralysis as in Chapter 3 we obtain the following results for the matrix elements
$\langle f| T_{2}(E)|i\rangle=\frac{-4}{m_{e} \Delta q} \int_{0<q \varepsilon^{2} \leqslant E^{2}} \frac{d q q_{12}^{*}(q) q_{1}(q)}{\left(1 / q^{2}\right)^{2 / 2}\left(1+q^{2}\right)^{1 / 2}\left(1+\frac{1}{2} z\right)^{1 / 2}} \frac{\exp (10 \omega)}{1-\exp (-2 \pi N)}(4.4)$
where

$$
\begin{equation*}
z=\frac{2\left(E-q^{2}\right) \Delta q^{2}}{\left(1+q^{2}\right)\left(4 / 4+q^{2}\right)} \tag{4.5}
\end{equation*}
$$

and $\omega$ and $\nu$ are as defined in $(3.22 b, c)$.

$\omega$ and $\nu$ are defined in (3.26b) ard (3.29), and $q_{3}{ }^{2}$ and $q_{23}^{\prime 2}$ we defined in Equations $(3.31 a, b)$. The momentum transfer $\Delta q$ is giver. in atomic units by

$$
\begin{equation*}
\Delta q^{2}=q i^{2}+q r^{2}-2 q ; q=\cos \theta \tag{4.8}
\end{equation*}
$$

where from (4.2)

$$
\begin{equation*}
q i^{2}=q f^{2}+\frac{3}{4} \tag{4.9}
\end{equation*}
$$

Equations (4.4) and (4.6) hold generally for all $n=1 \rightarrow 2$ transitions. It only remains to consider specific transitions and to insert into these equations the $r \in l e v a n t$ wave functions
a) $1 s-2 s$ transition
The $2 s$ state wavefurctior of hydrogen in momentum representation is

$$
\begin{equation*}
\phi_{200}(q)=\frac{1}{\pi} \frac{q^{2}-1 / 4}{\left(q^{2}+1 / 4\right)^{3}} \tag{4.10}
\end{equation*}
$$

The wavefurction is independent of angle so we obtain once again a single integral in the expression for the electron-proton term ard a triple integral for the electron-electron term. The resulting contributions to the scattering amplitude are
$f_{2}^{c}(E, \theta)=\frac{32 \sqrt{2}}{\Delta q} \int_{0}^{\varepsilon^{1 / 2}} \frac{d a q^{2}\left(q^{2}-1 / 4\right)}{\left(q^{2}+1 / 4\right)^{1 / 2}\left(q^{2}+1\right)^{5 / 2}(1+1 / 2 z)^{1 / 2}} \frac{\exp (i v \omega)}{1-\exp (-2 \pi v)}$
$\left.F_{3}^{c}\left(E_{1} \theta\right)=\frac{-4 \sqrt{2}}{\Delta q} \int_{0} \int \frac{d q_{3}\left(q_{23}^{2}+1 / 4\right)^{1 / 2}\left(q_{23}^{1 / 2}+1\right)^{5 / 2}(1+1 / 2 z)^{1 / 2}}{} \frac{\left.\operatorname{quxp}^{2}-1 / 4 v \omega\right) \exp (-2 \pi v)}{1-\exp (-2 \pi v)}+12\right)$
$0 \Delta q_{3} 1<(2 E)^{1 / 2}$

## b) $I_{s}-2 p$ transitions

The wavefunctions of the three sublevels of the $Z_{p}$ states of hydrogen are

$$
\begin{array}{ll}
m=0 ; & \phi_{210}(q)=\frac{1}{\pi} \frac{q}{\left(q^{2}+1 / 4\right)^{3} \cos \theta} \\
m= \pm 1 ; & \phi_{21 \pm 1}(q)=\frac{1}{\pi \sqrt{2}} \frac{q}{\left(q^{2}+1 / 4\right)^{3}} \sin \theta e^{ \pm i \phi} \quad \text { (4.13b) }
\end{array}
$$

The final state wave function is the only factor in Equation (4.4) with angular dependence. On performing

$$
\begin{equation*}
\langle F| T_{2}(F)|i\rangle=0 \tag{1,.14}
\end{equation*}
$$

and here the contribution to the scattering amplitude for the is -ip transition from the electrcr-protor. interaction is zero.

Therefore the orly contribution to tide $1 s-2 p$ cross section is from the electron-electrcn paths. Ne have seer for elastic scattering that at large angles of scattering these paths contribute a negligible amount to the cross section and there is nothing different about the inelastic process which could alter this fact. We therefore expect that in this approximation the contributions to the $n=1 \rightarrow 2$ cross section from $\mid s-2 p$ transitions will be underestimated, and for this reason we place less importance on our $1 s-2 p$ calculations than on the is $-2 s$ calculations.

We must take care in formulating the angular part of the electron-electron contribution to the $l s-2 p$ transition amplitude. The angular integration in Equation (4.6) is over the vector $q_{3}$ whereas the final state wavefunction is defined by $q_{23}=q_{3}+q_{5}$. We must relate the polar coordinates $\left(\theta^{\prime}, \phi^{\prime}\right)$ of $q_{23}$ to those, $(\theta, \phi)$, of $q_{3}$ in order to simplify the integration. Figure (4.1) shows the orientations of $q_{3}, q_{23}$ and $q_{5}$, and on taking components of these vectors along the $x, y$ and $\dot{z}$ axes we obtain the following coordinate relations

## FIGURE 4.1

The orientation of the vectors $q_{p}, q_{F}$ and $q_{23}=q_{5}+q_{f}$. $q_{3}$ has polar coordinates ( $q_{p}, \theta, \phi$ ).
If has polar coordinates $(q g, \theta / 2,0)$.
$q_{23}$ has polar coordinates ( $q_{23}, q^{\prime}, \phi^{\prime}$ ).

$$
\begin{align*}
& \cos \theta^{\prime}=-\frac{q_{F} \cos \theta_{2}+q_{3} \cos \theta}{q_{23}}  \tag{4.15a}\\
& \sin \theta^{\prime}=\frac{q_{3 F}}{q_{23}}  \tag{4.15b}\\
& \cos \phi^{\prime}=\frac{-q_{3} \sin \theta \cos \phi}{q_{3 F}}  \tag{4.15c}\\
& \sin \phi^{\prime}=\frac{-q_{5} \sin \theta_{2}+q_{3} \sin \theta_{\sin } \phi}{q_{3 F}} \tag{4.15d}
\end{align*}
$$

where

$$
q_{3 F}=\left(q_{3}^{2} \sin ^{2} \theta_{+}+q_{F}^{2} \sin ^{2} \theta / 2+2 q_{3} q_{F} \sin \theta / 2 \sin \theta \sin \phi\right)^{1 / 2}(4.16)
$$

The contribution to the scattering amplitude from the Is $-2 p(m=0)$ transition is from Equations (4.6), (4.13a) and (4.15a)
$f_{3,0}^{c}(E, \theta)$

and from Equations ( $4.15 b, c, d$ ) we obtain from
transitions to the $m= \pm 1$ levels
$F_{3, \pm 1}^{c}(E, \theta)$
$=\frac{4}{\pi \Delta q^{2}} \int d q_{3} \frac{q_{3 F}\left[\cos \left(\nu \omega \pm \phi^{\prime}\right)-i \sin \left(\nu \omega \pm \phi^{\prime}\right)\right] \exp (-2 \pi \nu)(4.18)}{\left(q_{23}{ }^{2}+1 / 4\right)^{7 / 2}\left(q^{12}+1\right)^{5 / 2}\left(1+t_{2}\right)^{1 / 2}(1-\exp (2 \nu))}$
L. 2 The Pole and Born Terms

Insertion of the Bor. term of the two-body Coulomb $T$ matrix into Equation (4.3a) for the electron-proton
matrix elemert lads to a zero contribution for all final state waverurctions $\phi_{2 e m}(\underline{q})$. The twe-tody
$T$ matrix is independent of the variable of interration, and the initial and final state wavefunctions are orthoforal in each case. The orly contributior to the scattering amplitude ccmes from the electron-electron interaction, and we can assume that these contributions will be small. We have calculated aralytically the Born term for the ls-2s interaction, ard fourd that it is equal to the result achieved using the first Bcrr approximation.

The pole terms are simply calculated and are similar in form to the pole terms for elastic scattering, apart fror the slight modificatiors needed for inelastic scattering which appeared in the aralysis for the classical path terms. In the $1 s-2 s$ trarsition there are contributions from both the electron-protor and the electrcr-electron interactions, but for $1 s-2 p$ transitiors only the latter term cortributes.

The cancellation between the pole term and the Borr term is not so ccmplete for the $\mathrm{ls}-2 \mathrm{~s}$ transition as for elastic scattering. This is largely due to the zero contribution from the electron-proton Bcrn term. Thus at an energy of 200 ev and a scattering angle of $20^{\circ}$, the differential crcss section would be halved by inclusion of the Born and pole terms rather than using
sol.ly the classical path terms. However, at a scattering argle of $60^{\circ}$ the effect of these two terms is neglifible, ard at high energies, for instarice, 1500 cv , their effect is small for scattering angles above $20^{\circ}$.

Can we say that the or-shell correspondence ider.tity holds for the ls-2s transitior? For small scattering angles we would not expect the ider.tity to be true. For low energies ( $\sim 200 \mathrm{e}$ ) in the erergy range corsidered we have seen that the idertity is not satisfied as closely as for elastic scattering, thougt. within an order of magritude the arproximation is good. For higher erergies the corresponderce identity is satisfied over the whole argilar rarge considered. 'Nith these reservations we shall apply the classical path terms in the Faddeev equations to calculate differential cross sections for erergies above 200 ev and scattering argles greater than $20^{\circ}$.

For $1 s-2 p$ transitions we have already stated that the contributiors from the Born, pole and classical path terms are likely to be irsignificant in comparison with the $1 s-2 s$ contributions to the scattering amplitude. Other than attempting to explain this pheromena physically, we shall neglect all contributions frcm the is $-2 p$ transition, so that the rest of this chapter will in the main be concerned with the $1 s-2 s$ transition.
4.3 Results ard Disclission

Equations (4.11), (4.12), (4.17) and (4.18) have been solved numerically using the computatior.al techriques described in the section or elastic scattering. The electror-electron terms, for toth the $15-2 s$ ard the Is-2p transitiors, are found to be numerically insignificant in comparisor. with the electron-proton term for the $\mathrm{ls}-2 \mathrm{~s}$ transition. The following results are calculated from the latter term which is the sole contribution of sigrificance in the classical path approximation. In figures (4.2) and (4.3) we present the argular distributions of the differential cross sectior. at two incident particle energies; compar isor.s are made with the Borr and the Coulomb prcjected Borr. (Geltman and Hidalgo, 1971 , hereafter referred to as CPB) results.

It is immediately apparent that the argular behaviour of the Born differential cross sectior is very different from the similar behaviour predicted by the other two theories. This is a result of the artificial cancellation of the electron-proton interaction in the first Borr approximation. As stated in Chapter 3, large angle scatterings are caused by the incident particle passing close to the nucleus, in which case the electron-electron contributior to the cross section is small. This explains why the Borr approximation gives reasonable results for small argles of scattering, but urderestimates the cross sectior greatly at angles above $60^{\circ}$

## FIGURE + 2

## FIGURE 4.3

The angular distribution of the differential cross section for the collision $e^{-}+H(1 s) \rightarrow e^{-}+H(2 s)$ ar incident energy 1500 ev .

#### Abstract

Alihough at large argles of scattering the anfular distribution of the classical path term cross section is very similar tj that of the CPB approximation, their macritudes differ widely. At both $200 e v$ ard 1500 ev the classical path term predicts a cross sectior higher than that of the CFB approximation, and there is no apparer.t convergerce of the two results at high erergies. Recent calculations using a polarised orbital distorted wave method (MicDowell et.al., 1973) predict cross sections close to the CFB result at 200 ev .

For small angle scattering the classical path cross sectior. peaks in the forwamd directior. wh.ilst the Born and CFB results converge to a corstant. The classical path cross section is however finite at zero scattering argle since the momentum trarsfer is nor-zero in this limit, and as has beer mertiored, the inclusion of the pole and Borr. terms reduces the cross section at small scattering angles. The zero argle behaviour is still differert from the Bcrr. and CFB behaviour even if these terms are included, a prorounced peaking in the forward direction resulting.

It was stated in Paper III of the serjes (Hutton, 1972) that by using a different form for $g\left(T T^{\prime}\right)$ in (4.3a), one obtains a differertial cross section closer in magnitude to the CPB result. This choice of $3\left(T_{1} T^{\prime}\right)$ is arbitory and as for elastic scattering we reiterate that a unique definitior of $Z\left(T, T^{\prime}\right)$ leads to the correct result given by Equation (4.11).

We have already stated that the is $-2 p$ differertial cross section contributes a negligitle amour.t to the
$n=1 \rightarrow 2$ cross section. Taking the results
presented in Figure (1..2) to be the $n=1 \rightarrow 2$ cross section at 2CCev, our value is still ar order of magritude higher than the CPB result, though the aneular distributiors are almost idertical at large scattering argles. The experinertal results quoted by Geltmar ard Hidalgo (Williams, l9€9) are normalised to the CFB approximation, so that the magnitude of the differertial cross sectior. is rot definite.

For a fixed scatterirg angle the enesgy dependerce of the differertial cross section using the CFB approximatior. is $E^{-3}$, whereas the Born result goes asymptotically as $E^{-6}$ for $\mathrm{ls}-2 s$ excitation and $E^{-7}$ for $1 s-2 p$. We have supposed that the classical path approximation has the asymptotic energy deperdence

## $\frac{d \sigma}{d \theta} \overline{\bar{E} \rightarrow \infty} \alpha(\theta) E^{-n}$

and have plotted $\log \left(\frac{d \delta}{d \Omega}\right)$ against $\log E$ for several fixed values of the scattering angle. A typical result is show in Figure ( 4.4 ) for $\theta=90^{\circ}$. Deviation from the correct straight line behaviour is only apparent at
$E<500 e v$. The value of $\Omega$ is given by the gradient of the line, and in Figure (4.5) we tabulate the values of $n$ obtained at different scattering angles. Within the error involved in measuring the gradier.t, we see that
n lies between 3.1 and 3.2 , ard no regular dependence on the scattering angle is apparent. The behaviour of

presented in Figure (1,.2) to be the $n=1 \rightarrow 2$ cross section at $200 e v$, our value is still ar order of magnitude higher than the CPB result, though the angular distributions are almost ideritical at large scattering angles. The experimental results quoted by Geltmar ard Hidalgo (Williams, 1969) are normalised to the CPB approximation, so that the magnitude of the differential cross section is not definite.

For a fixed scattering angle the energy dependence of the differential cross section using the CPB approximation. is $E^{-3}$, whereas the Born result goes asymptotically as $E^{-6}$ for $1 s-2 s$ excitation and $E^{-7}$ for $1 s-2 p$. We have supposed that the classical path approximation has the asymptotic energy deper.dence

## $\frac{d \sigma}{d \Omega}=\overline{E \rightarrow \infty} \alpha(\theta) E^{-n}$

 (4.19) and have plotted $\log \left(\frac{d g}{d U_{2}}\right)$ against $\log E$ for several fixed values of the scattering angle. A typical result is shown in Figure (4.4) for $\theta=90^{\circ}$. Deviation from the correct straight line behaviour is only apparent at $E<5000$. The value of $n$ is given by the gradient of the line, and in Figure ( 4.5 ) we tabulate the values of $n$ obtained at different scattering angles. Within the error involved in measuring the gradient, we see that $\cap$ lies between 3.1 and 3.2 , and no regular dependence on the scattering angle is apparent. The behaviour ofFIGURE 4.4

## FIGURE 4.5

the differential cross section at high energies is therefore very close to the CFB approximation behaviour, and confirms the discrepancy between the latter and the Born result.

This result is particularly importar.t. The different limiting energy dependence of the CFB approximation and the Bor approximation is shown. to be a result of the classical path part of the $T$ matrix. The $E^{-6}$ behaviour of the Born term is cancelled by an equal but opposite contribution from the pole term, leaving the classical path term to dictate the asymptotic energy behaviour. Experimental investigations are needed to establish the correct limiting energy dependence of the differential cross section at nonzero scattering angles.

### 4.4 The Coulomb nroiected Born approximation

This approximation was originally formulated for rearrangement collisions (Geltman, 1971) and was modified by Geltmar and Hidalgo to describe the excitation of hydrogen atoms by electrons. The transition amplitude between initial and final states is given in coordinate representation by

Here the incident and bound electron coordinates are given respectively by $\underline{r}_{1}$ and $\underline{r}_{2}$ with respect to the proton which is considered fixed at the origin. $\tilde{\Psi}_{F}\left(\underline{r}_{1}, r_{2}\right)$ is the solution of the scattering problem obtained if one ignores the electron-electron contribution $\frac{e^{2}}{\mid\left[1-\sum_{2} \mid\right.}$,
and $\exp \left(i q_{i}-r_{1}\right) \phi_{i}\left(\underline{r}_{2}\right)$
for the electron and atom at infinite separation.
Esser.tially the CFB approximation evaluates the matrix element of the repulsive interaction, ard allows for the distortion effect of the electror-protor interaction by including it in the final state wave furction. By doing this the CFB affroximatior avoids the incorrect sharp decrease of the differential cross section at intermediate scattering argles predicted by the first Born approximation.

We have transformed the CPB approximation for excitation into the barycer.tric momentum representation and obtained the following expression for the scattering amplitude. $f^{C P D}(E, \theta)=d^{x}$

$$
x \int \frac{q_{1}}{q_{1}} d q_{23} \frac{\phi_{F^{*}}\left(q_{23}\right) \phi i\left(q_{23}+q_{1}-q_{i}\right)}{\left(q_{1}-q_{i}\right)^{2}\left(q_{1}-q_{F}\right)^{2}\left(q_{1}{ }^{2}-q_{F^{2}}\right)^{2}}\left[1+\frac{2 q_{f} \cdot\left(q_{f}-q_{1}\right)}{q_{1}{ }^{2}-q_{F^{2}}}\right]^{-i \alpha}(4.21)
$$ where $C$ is the constant $\frac{m_{0} e^{2}}{n^{3}}\left(\frac{1}{2 \pi}\right)^{1 / 2} \exp (-1 / 2 n \alpha) \Gamma(1+i \alpha) \alpha q_{f}$ and $\alpha$ is the Coulomb interaction parameter $-e^{2} m_{e} / q_{f}$. The scattering amplitude in the first order Faddeev approximation involves a sum of two terms, both of which are single integrals over a momentum vector. In the CPB approximation $f^{C P B}(E, \theta)$ is an integral over two momentum vectors, but is a single term. This difference in the expressions for the scattering amplitude makes a formal comparison of the two theories difficult, however there are certain similarities which we note below.

At higr. energies the Coulomb factor $\alpha=-\nu$. On making the identification

$$
\begin{equation*}
1+\frac{2 q_{k} \cdot\left(q_{c}-q_{1}\right)}{q_{1}{ }^{2}-q_{6}^{2}}=1+z^{\prime}=\cosh \omega^{\prime} \tag{4.22}
\end{equation*}
$$

we obtain in the integrard a factor

$$
e^{i v \omega^{\prime}}\left[1+i \nu e^{-2 \omega^{\prime}}+\frac{i v(i v-1)}{2!} e^{-4 \omega^{\prime}}+\cdots \cdot\right]
$$ We cannot iderifify $z^{\prime}$ and $\omega^{\prime}$ with $z$ and ' $\omega$, but can see that factors similar to the classical path term and the pole terins do appear in Equation (4.23). The fact that these terrs carnot be separated out in the CPB approximation, is probably due to the mixing of momer.tum ccordinates inherent in the double irtegral of Equation (4.21). The similar areular distributions of the CFB ard Faddeev cross sections for inelastic scattering suggest that a formal comparison of the two theories may be possible, and further research along these lines wculd be profitable.

### 4.5 Concluding Remarks

We mentior. briefly here three phenomera which merit further investigation. Firstly that at high energies the electron-proton classical path contribution to the ls-2s differential cross section tends, to zero. It thus paradoxically appears to approach the Born result in the high energy limit. We have been unable to show aralytically that the electron-electron classical path contribution approashes the corresponding Born term at high energies, but it appears numerically that this may

At hift energies the Coulomb factor $\alpha=-\nu$. On making the identification

$$
\begin{equation*}
1+\frac{2 q_{F} \cdot\left(q_{c}-q_{1}\right)}{q_{1}^{2}-q^{2}}=1+z^{\prime}=\cosh w^{\prime} \tag{4.22}
\end{equation*}
$$

we obtain in the integrard a factor

$$
e^{i v \omega^{\prime}}\left[1+i \nu e^{-2 \omega^{\prime}}+\frac{i \nu(i \nu-1)}{2!} e^{-4 \omega^{\prime}}+\cdots\right] \quad \text { (4.23) }
$$

We cannot idertify $z^{\prime}$ and $\omega^{\prime}$ with $z$ and $\omega$, but can see that factors similar to the classical path term and the pole terms do appear in Equation (4.23). The fact that these terms carnot be separated out in the CPB approximation, is probably due to the mixing of momer.tum cocrdinates inherent in the double integral of Equatior (4.21). The similar argular distributiors of the CFB and Faddeev cross sections for inelastic scattering suggest that a formal comparison of the two theories may be possible, and further research along these lines wculd be profitable.

## 4. 5 Concluding Remarks

We mentior briefly here three phenomera which merit further investigatior. Firstly that at high energies the electron-proton classical path contribution to the Is-2s differential cross section tends, to zero. It thus paradoxically appears to approach the Born result in the high energy limit. We have been unable to show aralytically that the electron-electron classical path contribution approaches the corresponding Born term at high energies, but it appears numerically that this may
be the case. It would be strange if in the Faddecv formalism the same error appeared which makes the Born approximation unreliable for the calculation of differential cross sections, at large scattering argles, for inelastic scattering.

Secondly, and related to the latter phenomena, we consider the effect on the calculations of allowing the proton mass to be finite. The scattering process then needs a different description though many of the results are uncharged. Chen (1971) and ourselves have shown indepe:der.tly that the effect of a finite mass proton on elastic scattering calculations is to alter the asymptotic energy dependence of the differential cross section from $E^{-2}$ to $E^{-6}$. The proton, which is now free to move, absorbs recoil energy, thereby accelerating the decrease of the differential cross section with respect to energy.

More importantly for inelastic scattering, the inclusion of a finite mass proton in the theory would mean. that the electron-proton contribution to the Born term for the

Is -2 s transition, to the high energy limit of the classical path approximation for the $15-2 s$ transition, and to the Is $-2 p$ transition were all no longer zero. The infinite mass approximation is good for elastic scattering and $1 s-2 s$ excitation, but for the $\mid s-2 p$ transition when the electron-electron interactions are small, the inclusion of the finite mass of the proton would significantly alter the results.

Finally, having shown that the differertial cross section is finite at sinall anfles for inelastic scattering, we ask whether we can predict correct total cross sections. The classical path calculation of the differential cross section is strorgly peaked for forward scattering, and therefore the integrated cross section is overestimated. if calculated from this term alone. By including all three parts of the Coulomb $T$ matrix one may in principle be able to predict the correct zero argle behaviour, in which case the integrated cross sectior. would also be correct. However, there still remains the apparent over estimatior of the differential cross section by the first order iterate of the Faddeev equations, ar effect which it appears car. be overccme by including second order terms (Chen et.al., 1973). We therefore assume that the first order iterate of the Faddeev equations is insufficiently accurate to predict correct total cross sections.

## CHAFTER 5

## CONCLUDING REN.ARKS

### 2.1 Rearrancemert Collisions

Controversy over the correct limitirg erergy dependerce of the tolal cross section for electron exchange processes such as proton impact on hydrogen atcms has existed for mary years. In a review article, (Bransden, 1965), it is demonstrated that even within the first Born approximation ambiguities exist as to what is tive correct energy behaviour. Brinkman and Kramers (1930) arpued that the internuclear potential should not contritute tc the cross section to order $\mathrm{me} / \mathrm{mp}_{\mathrm{p}}$ where $\mathrm{mp}_{\mathrm{p}}$ is the mass of the proton. Bates and Dalgarno(1952) included the interruclear potential
in their calculations and found that the limiting energy dependence of this term was equal to that of the Brinkman-Kramers term and its effect was to reduce the cross section by one third. The second Born calculation of Drisko (1955) indicated a different asymptotic limit altogether from the first Born approxirration.

It was thus hoped that the Faddeev approach would resolve these ambiguities inherent in the Born approximation. In the Faddeev equations occurred the two-body off-shell $T$ matrix for the proton-proton interaction, and it was reasonably hoped that this term would be considerably smaller than the bare potential term. Bransden has
shown that at high energies the scattering is confined almost entirely to the forward direction. We have shown for direct collisions that the classical patt. term of the $T$ matrix is of no use for predicting differential cross sections at small ancles of scattering. The use of this term in the Faddeev єquations for rearrangement collisions is therefore ruled out.

Chen (1972) has reviewed the work of his group on rearrangerment collisions. It appears that ir the first order Iterate of the Faddeev equations the limiting energy behaviour of the cross section lies between the Brinkman-Kramer ar.d Bates-Dalgarno resulis. Furthermore it is shown that the second order terms of the Faddeev equations make significant contributions to the cross section, though all of these contrikutions are not evaluated. The Faddeev equations have up till now failed to resolve the ambiguities in the limiting energy dependence of the total cross section for rearrangement collisions.

### 5.2 The Faddeev Equations

We have applied the first order iterate of the Faddeev equations to both elastic and inelastic collisions at high energies. Comparison between our results and those of Chen and Sinfailan (1972) for the elastic differential cross section at energies above 200 ev and scattering angles above $30^{\circ}$, show that the classical path
approximation to the $T$ matrix is good. It therefore appears that for elastic scattering the first order Faddeev and Borr: approximations make considerably different pradictions for the magnitude of the differential cross section. Convergence of the two results is only apparent at energies an order of magnitude greater than that energy at which the Borri approximation is expected to be accurate. Experimertal investigations tentatively suggest that the differertial cross section is overestimated in the first order Faddeev approximation. For inelastic scattering the predictions of the Faddeev method improve on the Borr, in that the incorrect rapid decrease of the differertial cross section with angle is avcidel. The Faddeev differential cross section is greater in magnitude than that predicted by the Coulomt projected Bcrin result (Geltman and Hidalgo, 1971), though the angular and energy distributions of the two theories are very close.

As has been mentioned recent investigations of the second order term of the Faddeev expansion by Chen et.al. (1973) have suggested that there are important contributions to the differential cross section from lkis herm. The second order iterate of the Faddeev equations has been evaluated in the eikonal approximation using the angie approximation for the classical trajectories (Chen and Watson, 1969). Sirgularities appearing in the calculations for the first and second order terms
of the scrics cancel when the terms are summed. These singularities are associated with the difficulties involved in taking the on-shell limit of the Coulomb $T$ matrix. In the second order iterate of the Faddeev equations for elastic scattering at 200 ev , the differential cross section calculated in this way is very close to the prediction of the first order Borr approximation. We conclude therefore that the differential cross section for direct collision processes is overestimated by the first order iterate of the Faddeev equations.

### 5.3 The Coulomb TMatrix and the Significance of

 the Correspordence IdentitiesDue to the long range nature of the Coulomb potential singularities appear in the on-shell limit of the two-body off-shell Coulomb $T$ matrix. These singularities lead to factors in the differential cross section which are responsible for the difficulties mentioned in Section (5.2). The ambiguities in the definition of the differential cross section due to these factors referred to in the literature (Hutton and Rcberts,1972, Hutton 1972) have been removed. Singularities in the Coulomb $T$ matrix also appear at zero scattering angles for elastic scattering, and these lead to a small angle divergence of the differential cross section.

The on-shell correspondence identity for the Coulomb $T$ matrix (Roberts, 1971b) is shown to provide a goed
approxination when used to describe scattering phenomena at enerries above 2 COev arid scattering angles above $30^{\circ}$. Outside of this region quantal effects are important in the form of the Born and pole terms of the Coulomb $T$ matrix. The correspordence identity is related to the correspondence identity for the spectral operator (Norcliffe et.al. 1969b) so the latter is also showr. to stard up to a physical test. Classical considerations associated with these correspondence identities have been shown to contribute to the explaration of
i) the slow high energy convergence of the Born and Faddeev iifferential cross sections for elastic scattering.
ii) the differing erergy deperdences of the differential cross section for inelastic scatterirg predicted by the Bcrr, and Coulomb projected Born theorjes.
. Thus, despite the reservatiors about the application of the first order iterate of the Faddeev equations, the classical path approximation is shown to be a useful method, reducing the complication of calculations at high erergies and giving insight into the physics of direct atomic collision processes.

Calculation of the electron-electron ort of the Born T-matrix contribution to the elastic scattering amplitude

We need to evaluate
$\langle F| T_{3}{ }^{B}(E)|i\rangle=\frac{P_{c}}{2 n^{2} \mu_{12} \Delta_{q}^{2}} \int d q_{23} \phi_{1 S^{*}}\left(q_{1}+q_{q}\right) \phi_{15}\left(q_{3}+q_{i}\right)(A .1)$
It is convenient to transform to the dummy vector $\underline{x}$ given by

$$
\begin{equation*}
\underline{x}=q_{23}=q_{3}+q_{1} \tag{A.2}
\end{equation*}
$$

then (A.1) can be written

$$
\langle F| T_{3}^{0}(E)|i\rangle=\frac{p_{0}}{2 \pi^{2} m_{e} \Delta q^{2}} \int d \underline{x} \phi_{1 s^{*}}(\underline{x}) \phi_{1 s}(\underline{x}+\Delta q)(A .3)
$$

Inserting the expression for the momentum tace wave functions given by Equation (3.20) and performing the trivial angular part of the integration, we obtain in atomic units
$\langle F| T_{3}^{B}(E)|i\rangle=\frac{4}{\pi^{3} \text { me }^{4} q^{3}} \int_{0}^{\infty} \frac{d x x}{\left(x^{2}+1\right)^{2}} \times$

$$
\begin{equation*}
\times\left[\frac{1}{1+(x-\Delta q)^{2}}-\frac{1}{1+(x+\Delta q)^{2}}\right] \tag{A.4}
\end{equation*}
$$

The integrand is even so we can write

$$
\int_{0}^{\infty} d x x \ldots=\frac{1}{2} \int_{-\infty}^{\infty} d x x \ldots .
$$

Consider integrating the function $f(z)$ around the contour $C$ shown in Figure (A.1) where

$$
f(z)=\frac{z}{\left(z^{2}+1\right)^{2}\left[1+(z-\Delta q)^{2}\right]}
$$

Tree function $f(z)$ has poles inside $C$ at $z=i$ of order 2, and at $z=i+\Delta q$ of order 1. The residues are simply calculated by reference to Spiceel (p.172)

$$
R(i)=\frac{i(i-\Delta q)}{2\left[(i-\Delta q)^{2}+1\right]^{2}}
$$

and

$$
\begin{equation*}
R(i+\Delta q)=-\frac{i}{2} \quad \frac{i+\Delta q}{\left[1+(i-\Delta q)^{2}\right]^{2}} \tag{A.Єb}
\end{equation*}
$$

where $R(i)$ is the residue of the pole at $z=i$.

Similarly we integrate the function $g(z)$ around $C$ where

$$
\begin{equation*}
g(z)=\frac{z}{\left(z^{2}+1\right)^{2}\left[1+(z+\Delta q)^{2}\right]} \tag{A.7}
\end{equation*}
$$

and $g(z)$ has poles at $z=i$ of order 2, and at $z=i-\Delta q$ of order 1 , both lying inside $C$. The residues of these poles are given by

$$
\begin{align*}
R(i) & =\frac{-i(i+\Delta q)}{2\left[(i+\Delta q)^{2}+1\right]^{2}} \\
R(i-\Delta q) & =\frac{i(i-\Delta q)}{2\left[(i-\Delta q)^{2}+1\right]^{2}}
\end{align*}
$$

Now letting $R \rightarrow \infty$ and noting that the contribution from the curved part of the contour $C$ tends to zero in this limit (Spiegel, p.174) we have using the residue theorem

$$
\begin{equation*}
\langle F| T_{3}^{B}(E)|i\rangle=\frac{8}{\pi^{2} m_{c} \Delta q^{2}\left(\Delta q^{2}+4\right)^{2}} \tag{A.9}
\end{equation*}
$$
